[1] ANGELOPOULOS 98E measures the asymmetry $A_T = [\Gamma(\overline{K}^0_{t=0} \to e^+\pi^-\nu_{t=\tau}) - \Gamma(K^0_{t=0} \to e^-\pi^+\overline{\nu}_{t=\tau})]/[\Gamma(\overline{K}^0_{t=0} \to e^+\pi^-\nu_{t=\tau}) + \Gamma(K^0_{t=0} \to e^-\pi^+\overline{\nu}_{t=\tau})]$ as a function of the neutral-kaon eigentime τ. The initial strangeness of the neutral kaon is tagged by the charge of the accompanying charged kaon in the reactions $p\overline{p} \to K^-\pi^+K^0$ and $p\overline{p} \to K^+\pi^-\overline{K}^0$. The strangeness at the time of the decay is tagged by the lepton charge. The reported result is the average value of A_T over the interval $1\tau_S < \tau < 20\tau_S$. From this value of A_T ANGELOPOULOS 01B, assuming CPT invariance in the $e\pi\nu$ decay amplitude, determine the T-violating as $\Delta S{=}\Delta S$ conserving parameter (for its definition, see Review below) $4\mathrm{Re}(\epsilon) = (6.2 \pm 1.4 \pm 1.0) \times 10^{-3}$.

CPT INVARIANCE TESTS IN NEUTRAL KAON DECAY

Revised 2003 by P. Bloch (CERN).

The time evolution of a neutral kaon state state is described by

$$\frac{d}{dt}\Psi = -i\Lambda\Psi \ , \qquad \Lambda \equiv M - \frac{i}{2}\Gamma \tag{1}$$

where M and Γ are Hermitian 2×2 matrices known as the mass and decay matrices. The corresponding eigenvalues are $\lambda_{L,S} = m_{L,S} - \frac{i}{2}\gamma_{L,S}$. CPT invariance requires the diagonal elements of Λ to be equal. The CPT-violation complex parameter δ is defined as

$$\delta = \frac{\Lambda_{\overline{K}^0\overline{K}^0} - \Lambda_{K^0K^0}}{2(\lambda_L - \lambda_S)} = \delta_\parallel \exp\left(i\phi_{SW}\right) + \delta_\perp \exp\left(i(\phi_{SW} + \frac{\pi}{2})\right) \tag{2}$$

where we have introduced the projections $\delta_\parallel$ and $\delta_\perp$ respectively parallel and perpendicular to the superweak direction $\phi_{SW} = \tan^{-1}(2\Delta m/\Delta\gamma)$, where $\Delta m = m_L - m_S$ and $\Delta\gamma = \gamma_S - \gamma_L$, the positive mass and width differences between K_L and K_S. These projections are linked to the mass and width difference between K^0 and $\overline{K}^0$:

$$\delta_\parallel = \frac{1}{4}\frac{\gamma_{K^0} - \gamma_{\overline{K}^0}}{\sqrt{\Delta m^2 + \left(\frac{\Delta\gamma}{2}\right)^2}} \ , \ \delta_\perp = \frac{1}{2}\frac{m_{K^0} - m_{\overline{K}^0}}{\sqrt{\Delta m^2 + \left(\frac{\Delta\gamma}{2}\right)^2}} \ . \tag{3}$$

$\mathrm{Re}(\delta)$ can be directly measured by studying the time evolution of the strangeness content of initially pure K^0 and $\overline{K}^0$ states, for example through the asymmetry

$$A_{CPT} = \frac{P[\overline{K}^0 \to \overline{K}^0(t)] - P[K^0 \to K^0(t)]}{P[\overline{K}^0 \to \overline{K}^0(t)] + P[K^0 \to K^0(t)]} = 4\mathrm{Re}(\delta) \tag{4}$$

where $P[a \to b(t)]$ is the probability that the pure initial state a is seen as state b at proper time t. This method has been used by tagging the initial strangeness with strong interactions and the final strangeness with the semileptonic decay (a more appropriate combination of semileptonic rates allows to be independent of any direct CPT violation in the decay itself) and yields today's best value of $\mathrm{Re}(\delta)$, compatible with zero with an error of $\sim 3\times 10^{-4}$.

As an alternative it has been proposed to compare the semileptonic charge asymmetries for K_L and K_S

$$\delta_{L,S} = \frac{R(K_{L,S} \to \pi^-\ell^+\nu) - R(K_{L,S} \to \pi^+\ell^-\overline{\nu})}{R(K_{L,S} \to \pi^-\ell^+\nu) + R(K_{L,S} \to \pi^+\ell^-\overline{\nu})} \ ,$$
$$\delta_S - \delta_L = 4\mathrm{Re}(\delta) \ . \tag{5}$$

δ_L has been accurately measured and δ_S should be measured in the near future with tagged K_S at ϕ factories. Note however that Eq. (5) assumes CPT invariance in the $\Delta S = -\Delta Q$ semileptonic decay amplitude.

$\delta_\perp$ can be obtained from the measurement of the $\pi\pi$ decays CP-violation parameters η_{+-} and η_{00}. Figure 1 shows the various contributions to $\eta_{\pi\pi}$ [1]. The T-violation parameter ϵ_T

$$\epsilon_T = i\frac{|\Lambda_{K^0\overline{K}^0}|^2 - |\Lambda_{\overline{K}^0K^0}|^2}{\Delta\gamma(\lambda_L - \lambda_S)} \tag{6}$$

has been defined in such a way that it is exactly aligned along the superweak direction [‡]. A_I (resp. B_I) is the CPT-conserving (resp. violating) decay amplitude for the $\pi\pi$ Isospin I state, ε' is the direct CP/CPT-violation parameter $[\varepsilon' = 1/3(\eta_{+-} - \eta_{00})]$ and $\delta\phi = \frac{1}{2}\left[\varphi_\Gamma - \arg(A_0^*\overline{A}_0)\right]$ is the phase difference between

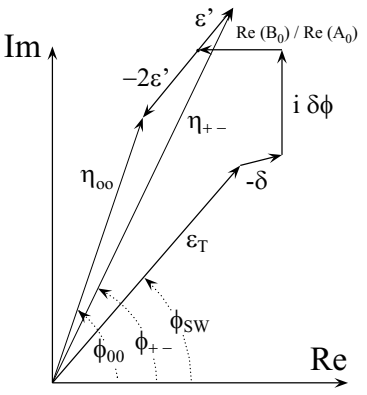

Figure 1: *CP*- and *CPT*-violation parameters in 2π decay.

the $I = 0$ component of the decay amplitude and the matrix element $\Gamma_{K^0\overline{K}^0}$. From Fig. 1 one obtains

$$\delta_\perp = |\eta_{+-}|(\phi_{SW} - \frac{2}{3}\phi_{+-} - \frac{1}{3}\phi_{00}) - \frac{\mathrm{Re}(B_0)}{\mathrm{Re}(A_0)}\sin(\phi_{SW}) + \delta\phi \quad \cos(\phi_{SW}) \ . \qquad (7)$$

The present accuracy on the term $|\eta_{+-}|(\phi_{SW} - \frac{2}{3}\phi_{+-} - \frac{1}{3}\phi_{00})$ is 2.6×10^{-5}. $\delta\phi$ gets contributions from *CP* violation in semileptonic and 3π decays [2,3] and can only be neglected at the present time if one assumes that η_{000} is not significantly larger than η_{+-0}. Furthermore, B_0 is not directly measured, so additional assumptions (for example, *CPT* conservation in the decay which implies $B_0 = 0$) or a combination with other measurements are necessary to obtain $\delta_\perp$.

If one assumes unitarity, one can measure $\mathrm{Im}(\delta)$ using the Bell-Steinberger relation which relates K_S and K_L decay amplitudes into all final states f:

$$\mathrm{Re}(\epsilon_T) - i\mathrm{Im}(\delta) = \frac{1}{2(i\Delta m + \frac{1}{2}(\gamma_L + \gamma_S))} \times \sum A_{f_L} A^*_{f_S} \ . \qquad (8)$$

Since the $\pi\pi$ amplitudes dominate, the result relies also strongly on the $\phi_{\pi\pi}$ phase measurements. The advantage is that B_0 does not enter. Using all available data, one obtains a value of $\mathrm{Im}(\delta)$ compatible with zero with a precision of 5×10^{-5}. The precision here is also limited by the poor measurement of η_{000}.

The results on $\mathrm{Re}(\delta)$ and $\mathrm{Im}(\delta)$ can be combined to obtain $\delta_\parallel$ and $\delta_\perp$ and therefore the K^0–$\overline{K}^0$ mass and width difference shown in Fig. 2. The current accuracy is a few 10^{-18} GeV for both.

If one assumes that *CPT* is conserved in the decays ($\gamma_{K^0} = \gamma_{\overline{K}^0}$, $\delta_\parallel = 0$, $B_I = 0$), the phase of δ is known, and the $\delta_\perp$ and Bell-Steinberger methods are identical. Assuming in addition

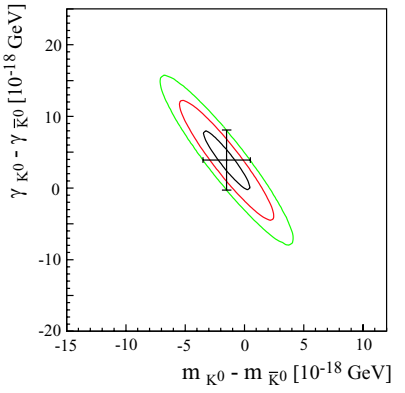

Figure 2: K^0–$\overline{K}^0$ mass vs width difference.

$\eta_{+-0} = \eta_{000}$, one in this case obtains a limit for $|m_{K^0} - m_{\overline{K}^0}|$ of 4.4×10^{-19} GeV (90%CL).

Footnotes and References

[‡] Many authors have a different definition of the T-violation parameter, $\epsilon = (\Lambda_{\overline{K}^0 K^0} - \Lambda_{K^0\overline{K}^0})/(2(\lambda_L - \lambda_S))$. ϵ is not exactly aligned with the superweak direction. The two definitions can be related through $\epsilon = \epsilon_T + i\delta\phi$.

CPT-VIOLATION PARAMETERS

In K^0-$\overline{K}^0$ mixing, if *CP*-violating interactions include a *T* conserving part then

$$|K_S\rangle = [|K_1\rangle + (\epsilon + \delta)|K_2\rangle]/\sqrt{1 + |\epsilon + \delta|^2}$$
$$|K_L\rangle = [|K_2\rangle + (\epsilon - \delta)|K_1\rangle]/\sqrt{1 + |\epsilon - \delta|^2}$$

where

$$|K_1\rangle = [|K^0\rangle + |\overline{K}^0\rangle]/\sqrt{2}$$
$$|K_2\rangle = [|K^0\rangle - |\overline{K}^0\rangle]/\sqrt{2}$$

and

$$|\overline{K}^0\rangle = CP|K^0\rangle.$$

The parameter δ specifies the *CPT*-violating part.

Estimates of δ are given below assuming the validity of the $\Delta S = \Delta Q$ rule. See also THOMSON 95 for a test of *CPT*-symmetry conservation in K^0 decays using the Bell-Steinberger relation.

REAL PART OF δ

A nonzero value violates *CPT* invariance.

[1] This ALAVI-HARATI 03 fit has Δm and τ_S free but constrains ϕ_{+-} to the Superweak value, i.e. assumes CPT. This τ_S value is correlated with their $\Delta m = m_{K^0_L} - m_{K^0_S}$ measurement in the K^0_L listings. The correlation coefficient $\rho(\tau_S, \Delta m) = -0.396$.
[2] The two ALAVI-HARATI 03 values use the same data. The first enters the "assuming CPT" fit and the second enters the "not assuming CPT" fit.
[3] This ALAVI-HARATI 03 fit has Δm, ϕ_{+-}, and τ_{K_S} free. See ϕ_{+-} in the "K_L CP violation" section for correlation information.
[4] ARONSON 82 find that K^0_S mean life may depend on the kaon energy.
[5] CARITHERS 75 measures the Δm dependence of the total decay rate (inverse mean life) to be $\Gamma(K^0_S) = [(1.122 \pm 0.004) + 0.16(\Delta m - 0.5348)/\Delta m]\, 10^{10}$/s, or, in terms of mean life, CARITHERS 75 measures $\tau_S = (0.8913 \pm 0.0032) - 0.238\,[\Delta m - 0.5348]$ (10^{-10} s). We have adjusted the measurement to use our best values of ($\Delta m = 0.5292 \pm 0.0010$) ($10^{10}$ $\hbar$ s^{-1}). Our first error is their experiment's error and our second error is the systematic error from using our best values.
[6] HILL 68 has been changed by the authors from the published value (0.865 ± 0.009) because of a correction in the shift due to η_{+-}. SKJEGGESTAD 72 and HILL 68 give detailed discussions of systematics encountered in this type of experiment.
[7] Pre-1971 experiments are excluded from the average because of disagreement with later more precise experiments.
[8] HILL 68 has been changed by the authors from the published value (0.865 ± 0.009) because of a correction in the shift due to η_{+-}. SKJEGGESTAD 72 and HILL 68 give detailed discussions of systematics encountered in this type of experiment.

CONSTRAINED FIT INFORMATION

An overall fit to 3 branching ratios uses 14 measurements and one constraint to determine 2 parameters. The overall fit has a $\chi^2 = 18.8$ for 13 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

[31] BATLEY 03 extrapolate also to the full kinematical region using a constant form factor and a vector matrix element. The resulting branching ratio is $(5.8^{+2.9}_{-2.4}) \times 10^{-9}$.

CP VIOLATION IN $K_S \to 3\pi$

Written 1996 by T. Nakada (Paul Scherrer Institute) and L. Wolfenstein (Carnegie-Mellon University).

The possible final states for the decay $K^0 \to \pi^+\pi^-\pi^0$ have isospin $I = 0$, 1, 2, and 3. The $I = 0$ and $I = 2$ states have $CP = +1$ and K_S can decay into them without violating CP symmetry, but they are expected to be strongly suppressed by centrifugal barrier effects. The $I = 1$ and $I = 3$ states, which have no centrifugal barrier, have $CP = -1$ so that the K_S decay to these requires CP violation.

In order to see CP violation in $K_S \to \pi^+\pi^-\pi^0$, it is necessary to observe the interference between K_S and K_L decay, which determines the amplitude ratio

$$\eta_{+-0} = \frac{A(K_S \to \pi^+\pi^-\pi^0)}{A(K_L \to \pi^+\pi^-\pi^0)} \ . \qquad (1)$$

If η_{+-0} is obtained from an integration over the whole Dalitz plot, there is no contribution from the $I = 0$ and $I = 2$ final states and a nonzero value of η_{+-0} is entirely due to CP violation.

Only $I = 1$ and $I = 3$ states, which are $CP = -1$, are allowed for $K^0 \to \pi^0\pi^0\pi^0$ decays and the decay of K_S into $3\pi^0$ is an unambiguous sign of CP violation. Similarly to η_{+-0}, η_{000} is defined as

$$\eta_{000} = \frac{A(K_S \to \pi^0\pi^0\pi^0)}{A(K_L \to \pi^0\pi^0\pi^0)} \ . \qquad (2)$$

If one assumes that CPT invariance holds and that there are no transitions to $I = 3$ (or to nonsymmetric $I = 1$ states), it can be shown that

$$\eta_{+-0} = \eta_{000} = \epsilon + i\frac{\mathrm{Im}\ a_1}{\mathrm{Re}\ a_1} \ . \qquad (3)$$

With the Wu-Yang phase convention, a_1 is the weak decay amplitude for K^0 into $I = 1$ final states; ϵ is determined from CP violation in $K_L \to 2\pi$ decays. The real parts of η_{+-0} and η_{000} are equal to $\mathrm{Re}(\epsilon)$. Since currently-known upper limits on $|\eta_{+-0}|$ and $|\eta_{000}|$ are much larger than $|\epsilon|$, they can be interpreted as upper limits on $\mathrm{Im}(\eta_{+-0})$ and $\mathrm{Im}(\eta_{000})$ and so as limits on the CP-violating phase of the decay amplitude a_1.

CP-VIOLATION PARAMETERS IN K^0_S DECAY

$\mathrm{Im}(\eta_{+-0})^2 = \Gamma(K^0_S \to \pi^+\pi^-\pi^0, CP\text{-violating}) / \Gamma(K^0_L \to \pi^+\pi^-\pi^0)$

CPT assumed valid (i.e. $\mathrm{Re}(\eta_{+-0}) \simeq 0$).

VALUE	CL%	EVTS	DOCUMENT ID		TECN
• • • We do not use the following data for averages, fits, limits, etc. • • •					
<0.23	90	601	[32] BARMIN	85	HLBC
<0.12	90	384	METCALF	72	ASPK

[32] BARMIN 85 find $\mathrm{Re}(\eta_{+-0}) = (0.05 \pm 0.17)$ and $\mathrm{Im}(\eta_{+-0}) = (0.15 \pm 0.33)$. Includes events of BALDO-CEOLIN 75.

$\mathrm{Im}(\eta_{+-0}) = \mathrm{Im}(A(K^0_S \to \pi^+\pi^-\pi^0, CP\text{-violating}) / A(K^0_L \to \pi^+\pi^-\pi^0))$

VALUE	EVTS	DOCUMENT ID		TECN	COMMENT
$-0.002 \pm 0.009^{+0.002}_{-0.001}$	500k	[33] ADLER	97B	CPLR	
• • • We do not use the following data for averages, fits, limits, etc. • • •					
$-0.002 \pm 0.018 \pm 0.003$	137k	[34] ADLER	96D	CPLR	Sup. by ADLER 97B
$-0.015 \pm 0.017 \pm 0.025$	272k	[35] ZOU	94	SPEC	

[33] ADLER 97B also find $\mathrm{Re}(\eta_{+-0}) = -0.002 \pm 0.007^{+0.004}_{-0.001}$. See also ANGELOPOULOS 98C.

[34] The ADLER 96D fit also yields $\mathrm{Re}(\eta_{+-0}) = 0.006 \pm 0.013 \pm 0.001$ with a correlation $+0.66$ between real and imaginary parts. Their results correspond to $|\eta_{+-0}| < 0.037$ with 90% CL.

[35] ZOU 94 use theoretical constraint $\mathrm{Re}(\eta_{+-0}) = \mathrm{Re}(\epsilon) = 0.0016$. Without this constraint they find $\mathrm{Im}(\eta_{+-0}) = 0.019 \pm 0.061$ and $\mathrm{Re}(\eta_{+-0}) = 0.019 \pm 0.027$.

$\mathrm{Im}(\eta_{000})^2 = \Gamma(K^0_S \to 3\pi^0) / \Gamma(K^0_L \to 3\pi^0)$

CPT assumed valid (i.e. $\mathrm{Re}(\eta_{000}) \simeq 0$). This limit determines branching ratio $\Gamma(3\pi^0)/\Gamma_{total}$ above.

VALUE	CL%	EVTS	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •						
<0.1	90	632	[36] BARMIN	83	HLBC	
<0.28	90		[37] GJESDAL	74B	SPEC	Indirect meas.

[36] BARMIN 83 find $\mathrm{Re}(\eta_{000}) = (-0.08 \pm 0.18)$ and $\mathrm{Im}(\eta_{000}) = (-0.05 \pm 0.27)$. Assuming CPT invariance they obtain the limit quoted above.

[37] GJESDAL 74B uses $K2\pi$, $K_{\mu 3}$, and K_{e3} decay results, unitarity, and CPT. Calculates $|(\eta_{000})| = 0.26 \pm 0.20$. We convert to upper limit.

$\mathrm{Im}(\eta_{000}) = \mathrm{Im}(A(K^0_S \to \pi^0\pi^0\pi^0)/A(K^0_L \to \pi^0\pi^0\pi^0))$

$K^0_S \to \pi^0\pi^0\pi^0$ violates CP conservation, in contrast to $K^0_S \to \pi^+\pi^-\pi^0$ which has a CP-conserving part.

VALUE	EVTS	DOCUMENT ID		TECN
$-0.05 \pm 0.12 \pm 0.05$	17300	[38] ANGELOPO...	98B	CPLR

[38] ANGELOPOULOS 98B assumes $\mathrm{Re}(\eta_{000}) = \mathrm{Re}(\epsilon) = 1.635 \times 10^{-3}$. Without assuming CPT invariance, they obtain $\mathrm{Re}(\eta_{000}) = 0.18 \pm 0.14 \pm 0.06$ and $\mathrm{Im}(\eta_{000}) = 0.15 \pm 0.20 \pm 0.03$.

K^0_L $I(J^P) = \frac{1}{2}(0^-)$

$m_{K^0_L} - m_{K^0_S}$

For earlier measurements, beginning with GOOD 61 and FITCH 61, see our 1986 edition, Physics Letters **170B** 132 (1986).

OUR FIT is described in the note on "*CP* violation in K_L decays" in the K^0_L Particle Listings. The result labeled "OUR FIT Assuming *CPT*" ["OUR FIT Not assuming *CPT*"] includes all measurements except those with the comment "Not assuming *CPT*" ["Assuming *CPT*"]. Measurements with neither comment do not assume *CPT* and enter both fits.

[1] ALAVI-HARATI 03 fit Δm and $\tau_{K^0_S}$ simultaneously. ϕ_{+-} is constrained to the Superweak value, i.e. *CPT* is assumed. See "K^0_S Mean Life" section for correlation information.

[2] The two ALAVI-HARATI 03 values use the same data. The first enters the "Assuming *CPT*" fit and the second enters the "Not assuming *CPT*" fit. They use 40–160 GeV K beams.

[3] ALAVI-HARATI 03 fit Δm, ϕ_{+-}, and τ_{K_S} simultaneously. See ϕ_{+-} in the "K_L *CP* violation" section for correlation information.

[4] Fits Δm and ϕ_{+-} simultaneously. GIBBONS 93C systematic error is from B. Winstein via private communication. 20–160 GeV K beams.

[5] GIBBONS 93 value assume $\phi_{+-} = \phi_{00} = \phi_{SW} = (43.7 \pm 0.2)^\circ$, i.e. assumes *CPT*. 20–160 GeV K beams.

[6] These two experiments have a common systematic error due to the uncertainty in the momentum scale, as pointed out in WAHL 89.

[7] ANGELOPOULOS 01 uses strong interactions strangeness tagging at two different times.

[8] Uses $\overline{K}^0_{e3}$ and K^0_{e3} strangeness tagging at production and decay. Assumes *CPT* conservation on $\Delta S = -\Delta Q$ transitions.

[9] ADLER 96C is the result of a fit which includes nearly the same data as entered into the "OUR FIT" value above.

[10] ARONSON 82 find that Δm may depend on the kaon energy.

[11] ARONSON 70 and CARNEGIE 71 use K^0_S mean life $= (0.862 \pm 0.006) \times 10^{-10}$ s. We have not attempted to adjust these values for the subsequent change in the K^0_S mean life or in η_{+-}.

[a] The value is for the sum of the charge states or particle/antiparticle states indicated.

[b] Most of this radiative mode, the low-momentum γ part, is also included in the parent mode listed without γ's.

[c] See the Particle Listings below for the energy limits used in this measurement.

[d] Allowed by higher-order electroweak interactions.

[e] Violates *CP* in leading order. Test of direct *CP* violation since the indirect *CP*-violating and *CP*-conserving contributions are expected to be suppressed.

CONSTRAINED FIT INFORMATION

An overall fit to the mean life, 3 decay rate, and 15 branching ratios uses 50 measurements and one constraint to determine 9 parameters. The overall fit has a $\chi^2 = 43.7$ for 42 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \cdot \delta p_j)$, in percent, from the fit to parameters p_i, including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

2.1 ±0.6		14	[31] BARR	90C	NA31	$m_{\gamma\gamma}$ > 280 MeV

[28] LAI 02B reports 1.36 ± 0.03 ± 0.03 for $B(K^0_L \to \pi^0\pi^0) = 9.27\times10^{-4}$. We rescale to our best value $B(K^0_L \to \pi^0\pi^0) = (9.32 \pm 0.12)\times10^{-4}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. They also find that $B(\pi^0 2\gamma,\ m_{\gamma\gamma}$ <110 MeV) < 0.6×10^{-8}(90% CL).

[29] ALAVI-HARATI 99B finds that $\Gamma(\pi^0 2\gamma,\ m_{\gamma\gamma}$ <240 MeV)) / $\Gamma(\pi^0 2\gamma) = (17.3 \pm 1.3 \pm 1.5)\%$.

[30] BARR 92 find that $\Gamma(\pi^0 2\gamma,\ m_{\gamma\gamma}$ <240 MeV)/$\Gamma(\pi^0 2\gamma)$< 0.09 (90% CL).

[31] BARR 90C superseded by BARR 92.

[47] Quadratic dependence required by some experiments. (See sections on "QUADRATIC COEFFICIENT h" and "QUADRATIC COEFFICIENT k" below.) Correlations prevent us from averaging results of fits not including g, h, and k terms.

[48] BISI 74 value comes from quadratic fit with quad. term consistent with zero. g error is thus larger than if linear fit were used.

[49] BUCHANAN 70 result revised by BUCHANAN 75 to include radiative correlations and to use more reliable K^0_L momentum spectrum of second experiment (had same beam).

K^0_L FORM FACTORS

For discussion, see note on form factors in the $K^\pm$ section of the Particle Listings above.

In the form factor comments, the following symbols are used.

f_+ and f_- are form factors for the vector matrix element.
f_S and f_T refer to the scalar and tensor term.
$f_0 = f_+ + f_- t/(m^2_K - m^2_\pi)$.
λ_+, λ_-, and λ_0 are the linear expansion coefficients of f_+, f_-, and f_0.
λ_+ refers to the $K^0_{\mu3}$ value except in the K^0_{e3} sections.
$d\xi(0)/d\lambda_+$ is the correlation between $\xi(0)$ and λ_+ in $K^0_{\mu3}$.
$d\lambda_0/d\lambda_+$ is the correlation between λ_0 and λ_+ in $K^0_{\mu3}$.
t = momentum transfer to the π in units of m^2_π.
DP = Dalitz plot analysis.
PI = π spectrum analysis.
MU = μ spectrum analysis.
POL= μ polarization analysis.
BR = $K^0_{\mu3}/K^0_{e3}$ branching ratio analysis.
E = positron or electron spectrum analysis.
RC = radiative corrections.

λ_+ (LINEAR ENERGY DEPENDENCE OF f_+ IN $K^0_{\ell3}$ DECAY)

For radiative correction of K^0_{e3} DP, see GINSBERG 67 and BECHERRAWY 70. Results labeled OUR FIT are discussed in the review "$K^\pm_{\ell3}$ and $K^0_{\ell3}$ Form Factors" in the $K^\pm$ Listings.

$-0.68^{+0.12}_{-0.20}$	−26	16k	[59] CHIEN	70	ASPK	DP
+1.2 ±0.8	−18	1341	[61] CARPENTER	66	OSPK	DP

[53] BIRULEV 81 error, $d\xi(0)/d\lambda_+$ calculated by us from λ_0, λ_+. $d\lambda_0/d\lambda_+ = 0$ used.

[54] HILL 79 and CHO 80 calculated by us from λ_0, λ_+, and $d\lambda_0/d\lambda_+$.

[55] BUCHANAN 75 is calculated by us from λ_0, λ_+ and $d\lambda_0/d\lambda_+$ because their appendix A value -0.20 ± 22 assumes $\xi(t)$ constant, i.e. $\lambda_- = \lambda_+$.

[56] DONALDSON 74B gives $\xi = -0.11 \pm 0.02$ not including systematics. Above error and $d\xi(0)/d\lambda_+$ were calculated by us from λ_0 and λ_+ errors (which include systematics) and $d\lambda_0/d\lambda_+$.

[57] PEACH 73 gives $\xi(0) = -0.95 \pm 0.45$ for $\lambda_+ = \lambda_- = 0.025$. The above value is for $\lambda_- = 0$. K.Peach, private communication (1974).

[58] ALBROW 72 fit has λ_- free, gets $\lambda_- = -0.030 \pm 0.060$ or $\Lambda = +0.15^{+0.17}_{-0.11}$.

[59] CHIEN 70 errors are statistical only. $d\xi(0)/d\lambda_+$ from figure 4. DALLY 72 is a reanalysis of CHIEN 70. The DALLY 72 result is not compatible with assumption $\lambda_- = 0$ so not included in our fit. The nonzero λ_- value and the relatively large λ_+ value found by DALLY 72 come mainly from a single low t bin (figures 1,2). The (f_+,ξ) correlation was ignored. We estimate from figure 2 that fixing $\lambda_- = 0$ would give $\xi(0) = -1.4 \pm 0.3$ and would add 10 to χ^2. $d\xi(0)/d\lambda_+$ is not given.

[60] BASILE 70 is incompatible with all other results. Authors suggest that efficiency estimates might be responsible.

[61] CARPENTER 66 $\xi(0)$ is for $\lambda_+ = 0$. $d\xi(0)/d\lambda_+$ is from figure 9.

$\xi_B = f_-/f_+$ (determined from $K^0_{\mu 3}/K^0_{e3}$)

The $K^0_{\mu 3}/K^0_{e3}$ branching ratio fixes a relationship between $\xi(0)$ and λ_+ if μ-e universality is assumed. We quote the author's $\xi(0)$ and associated λ_+ but do not average because the λ_+ values differ. The result labeled OUR FIT below does not use these ξ_b values. Instead it uses the authors $K^0_{\mu 3}/K^0_{e3}$ branching ratios to obtain the fitted $K^0_{\mu 3}/K^0_{e3}$ ratio which is then converted to the KL3FIT value below, as discussed in the review "$K^{\pm}_{\ell 3}$ and $K^0_{\ell 3}$ Form Factors" in the $K^{\pm}$ Listings. ξ_B is $\xi(0)$ determined by Method *B* of that review. The parameter $\xi(0)$ is redundant with λ_0 below and is not put into the Meson Summary Table.

[62] KL3FIT value is from fitted $K^0_{\mu 3}/K^0_{e3}$ branching ratio. $d\xi(0)/d\lambda_+ = -10.2$.

[63] EVANS 73 replaces EVANS 69.

$\xi_C = f_-/f_+$ (determined from μ polarization in $K^0_{\mu 3}$)

The μ polarization is a measure of $\xi(t)$. No assumptions on λ_{+-} are necessary, but t (weighted by sensitivity to $\xi(t)$) should be specified. In λ_+, $\xi(0)$ parametrization this is $\xi(0)$ for $\lambda_+ = 0$. $d\xi/d\lambda = \xi t$. For radiative correction to μ polarization in $K^0_{\mu 3}$, see GINSBERG 73. Results labeled OUR FIT are discussed in the review "$K^{\pm}_{\ell 3}$ and $K^0_{\ell 3}$ Form Factors" in the $K^{\pm}$ Listings. ξ_C is $\xi(0)$ determined by Method *C* of that review. The parameter $\xi(0)$ is redundant with λ_0 below and is not put into the Meson Summary Table.

[68] KL3FIT 04 value is from our fitted value of the $K^{\pm}_{\mu 3}/K^{\pm}_{e3}$ branching ratio. Assumes $\mu - e$ universality.

[69] BIRULEV 81 gives $d\lambda_0/d\lambda_+ = -1.5$, giving an unreasonably narrow error ellipse which dominates all other results. We use $d\lambda_0/d\lambda_+ = 0$.

[70] λ_0 value is for $\lambda_+ = 0.03$ calculated by us from $\xi(0)$ and $d\xi(0)/d\lambda_+$.

[71] BUCHANAN 75 value is from their appendix A and uses only $K_{\mu 3}$ data. $d\lambda_0/d\lambda_+$ was obtained by private communication, C.Buchanan, 1976.

[72] DONALDSON 74B $d\lambda_0/d\lambda_+$ obtained from figure 18.

[73] CHO 80 BR result not independent of their Dalitz plot result.

[74] Fit for λ_0 does not include this value but instead includes the $K_{\mu 3}/K_{e3}$ result from this experiment.

[75] PEACH 73 assumes $\lambda_+ = 0.025$. Calculated by us from $\xi(0)$ and $d\xi(0)/d\lambda_+$.

[76] ALBROW 72 λ_0 is calculated by us from ξ_A, λ_+ and $d\xi(0)/d\lambda_+$. They give $\lambda_0 = -0.043 \pm 0.039$ for $\lambda_- = 0$. We use our larger calculated error.

[77] DALLY 72 gives $f_0 = 1.20 \pm 0.35$, $\lambda_0 = -0.080 \pm 0.272$, $\lambda_0{}' = -0.006 \pm 0.045$, but with a different definition of λ_0. Our quoted λ_0 is his λ_0/f_0. We cannot calculate true λ_0 error without his (λ_0, f_0) correlations. See also note on DALLY 72 in section ξ_A.

[78] BASILE 70 λ_0 is for $\lambda_+ = 0$. Calculated by us from ξ_A with $d\xi(0)/d\lambda_+ = 0$. BASILE 70 is incompatible with all other results. Authors suggest that efficiency estimates might be responsible.

$\alpha^{\rm eff}_{K^*}$ DECAY FORM FACTOR FOR $K_L \to e^+e^-e^+e^-$

$\alpha^{\rm eff}_{K^*}$ is the parameter describing the relative strength of an intermediate pseudoscalar decay amplitude and a vector meson decay amplitude in the model of BERGSTROM 83. It takes into account both the radiative effects and the form factor. Since there are two e^+e^- pairs here compared with one in $e^+e^-\gamma$ decays, a factorized expression is used for the $e^+e^-e^+e^-$ decay form factor.

CP VIOLATION IN K_L DECAYS

Revised March 2004 by L. Wolfenstein (Carnegie-Mellon University) and T.G. Trippe (LBNL).

The symmetries C (particle-antiparticle interchange) and P (space inversion) hold for strong and electromagnetic interactions. After the discovery of large C and P violation in the weak interactions, it appeared that the product CP was a good symmetry. In 1964 CP violation was observed in K^0 decays at a level given by the parameter $\epsilon \approx 2.3 \times 10^{-3}$.

A unified treatment of CP violation in K, D, B, and B_s mesons is given in "CP Violation in Meson Decays" by D. Kirkby and Y. Nir in this *Review*. A recent book by

K. Kleinknecht [1] gives a more detailed review including a thorough discussion of the experimental techniques used to determine CP violation parameters. Here we give a concise summary of the formalism needed to define the parameters of CP violation in K_L decays and a description of our fits for the best values of these parameters.

1. Formalism for CP violation in Kaon decay:

CP violation has been observed in the semi-leptonic decays $K_L^0 \to \pi^\mp \ell^\pm \nu$ and in the nonleptonic decay $K_L^0 \to 2\pi$. The experimental numbers that have been measured are

$$\delta_L = \frac{\Gamma(K_L^0 \to \pi^- \ell^+ \nu) - \Gamma(K_L^0 \to \pi^+ \ell^- \nu)}{\Gamma(K_L^0 \to \pi^- \ell^+ \nu) + \Gamma(K_L^0 \to \pi^+ \ell^- \nu)} \quad (1a)$$

$$\eta_{+-} = A(K_L^0 \to \pi^+\pi^-)/A(K_S^0 \to \pi^+\pi^-) = |\eta_{+-}|\, e^{i\phi_{+-}} \quad (1b)$$

$$\eta_{00} = A(K_L^0 \to \pi^0\pi^0)/A(K_S^0 \to \pi^0\pi^0) = |\eta_{00}|\, e^{i\phi_{00}} \ . \quad (1c)$$

CP violation can occur either in the K^0–$\overline{K}^0$ mixing or in the decay amplitudes. Assuming CPT invariance, the mass eigenstates of the K^0–$\overline{K}^0$ system can be written

$$|K_S\rangle = p|K^0\rangle + q|\overline{K}^0\rangle \ , \qquad |K_L\rangle = p|K^0\rangle - q|\overline{K}^0\rangle \ . \quad (2)$$

If CP invariance held, we would have $q = p$ so that K_S would be CP even and K_L CP odd. (We define $|\overline{K}^0\rangle$ as CP $|K^0\rangle$). CP violation in K^0–$\overline{K}^0$ mixing is then given by the parameter $\widetilde{\epsilon}$ where

$$\frac{p}{q} = \frac{(1+\widetilde{\epsilon})}{(1-\widetilde{\epsilon})} \ . \quad (3)$$

CP violation can also occur in the decay amplitudes

$$A(K^0 \to \pi\pi(I)) = A_I e^{i\delta_I} \ , \qquad A(\overline{K}^0 \to \pi\pi(I)) = A_I^* e^{i\delta_I} \ , \quad (4)$$

where I is the isospin of $\pi\pi$, δ_I is the final-state phase shift, and A_I would be real if CP invariance held. The CP-violating observables are usually expressed in terms of ϵ and ϵ' defined by

$$\eta_{+-} = \epsilon + \epsilon' \ , \qquad \eta_{00} = \epsilon - 2\epsilon' \ , \quad (5a)$$

One can then show [2]

$$\epsilon = \widetilde{\epsilon} + i\ (\mathrm{Im}\ A_0/\mathrm{Re}\ A_0) \ , \quad (5b)$$

$$\sqrt{2}\epsilon' = ie^{i(\delta_2-\delta_0)}(\mathrm{Re}\, A_2/\mathrm{Re}\, A_0)\ (\mathrm{Im}\, A_2/\mathrm{Re}\, A_2 - \mathrm{Im}\, A_0/\mathrm{Re}\, A_0) \ , \quad (5c)$$

$$\delta_L = 2\mathrm{Re}\,\epsilon/(1+|\epsilon|^2) \approx 2\mathrm{Re}\,\epsilon \ . \quad (5d)$$

In Eqs. (5a) small corrections of order $\epsilon' \times \mathrm{Re}\ (A_2/A_0)$ are neglected and Eq. (5d) assumes the $\Delta S = \Delta Q$ rule.

The quantities Im A_0, Im A_2, and Im $\widetilde{\epsilon}$ depend on the choice of phase convention since one can change the phases of K^0 and $\overline{K}^0$ by a transformation of the strange quark state $|s\rangle \to |s\rangle\, e^{i\alpha}$; of course, observables are unchanged. It is possible by a choice of phase convention to set Im A_0 or Im A_2 or Im $\widetilde{\epsilon}$ to zero, but none of these is zero with the usual phase conventions in the Standard Model. The choice Im $A_0 = 0$ is called the Wu-Yang phase convention [3] in which case $\epsilon = \widetilde{\epsilon}$. The value of ϵ' is independent of phase convention and a nonzero value demonstrates CP violation in the decay amplitudes, referred to as direct CP violation. The possibility that direct CP violation is essentially zero and that CP violation occurs only in the mixing matrix was referred to as the superweak theory [4].

By applying CPT invariance and unitarity the phase of ϵ is given approximately by

$$\phi_\epsilon \approx \tan^{-1}\frac{2(m_{K_L} - m_{K_S})}{\Gamma_{K_S} - \Gamma_{K_L}} \approx 43.51 \pm 0.05^\circ \quad (6a)$$

while Eq. (5c) gives the phase of ϵ' to be

$$\phi_{\epsilon'} = \delta_2 - \delta_0 + \frac{\pi}{2} \approx 48 \pm 4^\circ \ , \quad (6b)$$

where the numerical value is based on an analysis of π–π scattering [5]. The approximation in Eq. (6a) depends on the assumption that direct CP violation is very small in all K^0 decays. This is expected to be good to a few tenths of a degree as indicated by the small value of ϵ' and of η_{+-0}, the CP-violation parameter in the decay $K_S \to \pi^+\pi^-\pi^0$ [6], although limits on η_{000} are still poor. The relation in Eq. (6a) is exact in the superweak theory so this is sometimes called the superweak phase ϕ_{SW}. An important point for the analysis is that $\cos(\phi_{\epsilon'} - \phi_\epsilon) \simeq 1$. The consequence is that only two real quantities need be measured, the magnitude of ϵ and the value of (ϵ'/ϵ) including its sign. The measured quantity $|\eta_{00}/\eta_{+-}|^2$, which is very close to unity so that we can write

$$|\eta_{00}/\eta_{+-}|^2 \approx 1 - 6\mathrm{Re}\,(\epsilon'/\epsilon) \approx 1 - 6\epsilon'/\epsilon \ . \quad (7a)$$

$$\mathrm{Re}(\epsilon'/\epsilon) \approx \tfrac{1}{3}(1 - |\eta_{00}/\eta_{+-}|) \ . \quad (7b)$$

From the experimental measurements in this Edition of the *Review of Particle Physics* and the fits discussed in the next section, one finds

$$|\epsilon| = (2.284 \pm 0.014) \times 10^{-3} \ , \quad (8a)$$

$$\phi_\epsilon = (43.5 \pm 0.7)^\circ \ , \quad (8b)$$

$$\mathrm{Re}(\epsilon'/\epsilon) \approx \epsilon'/\epsilon = (1.67 \pm 0.26) \times 10^{-3} \ , \quad (8c)$$

$$\phi_{+-} = (43.4 \pm 0.7)^\circ \ , \quad (8d)$$

$$\phi_{00} - \phi_{+-} = (0.2 \pm 0.4)^\circ \ , \quad (8e)$$

$$\delta_L = (3.27 \pm 0.12) \times 10^{-3} \ . \quad (8f)$$

Direct CP violation, as indicated by ϵ'/ϵ, is expected in the Standard Model. However the numerical value cannot be reliably predicted because of theoretical uncertainties [7]. The value of δ_L agrees with Eq. (5d). The values of ϕ_{+-} and $\phi_{00} - \phi_{+-}$ are used to set limits on CPT violation. [See Tests of Conservation Laws.]

2. Fits for K_L^0 CP-violation parameters:

In recent years, K_L^0 CP-violation experiments have improved our knowledge of CP-violation parameters and their consistency with the expectations of CPT invariance and unitarity. To determine the best values of the CP-violation parameters in $K_L^0 \to \pi^+\pi^-$ and $\pi^0\pi^0$ decay, we make two types of

fits, one for the phases ϕ_{+-} and ϕ_{00} jointly with Δm and τ_S, and the other for the amplitudes $|\eta_{+-}|$ and $|\eta_{00}|$ jointly with the $K_L^0 \to \pi\pi$ branching fractions.

Fits to ϕ_{+-}, ϕ_{00}, $\Delta\phi$, Δm, and τ_S data: These are joint fits to the data on ϕ_{+-}, ϕ_{00}, the phase difference $\Delta\phi = \phi_{00} - \phi_{+-}$, the K_L^0–K_S^0 mass difference Δm, and the K_S^0 mean life τ_S, including the effects of correlations.

Measurements of ϕ_{+-} and ϕ_{00} are highly correlated with Δm and τ_S. Some measurements of τ_S are correlated with Δm. The correlations are given in the footnotes of the ϕ_{+-} and ϕ_{00} sections of the K_L^0 Particle Listings and the τ_S section of the K_S^0 Particle listings.

In most cases, the correlations are quoted as 100%, *i.e.*with the value and error of ϕ_{+-} or ϕ_{00} given at a fixed value of Δm and τ_S with additional terms specifying the dependence of the value on Δm and τ_S. These cases lead to diagonal bands in Figs. [1] and [2]. The KTeV experiment [8] quotes its results as values of ϕ_{+-}, Δm, and τ_S with correlations, leading to the ellipses labeled "b".

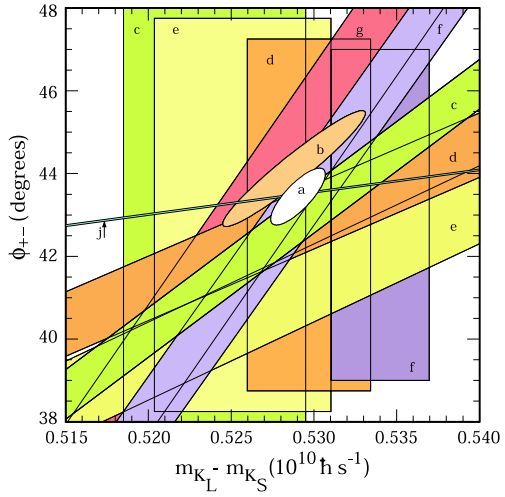

Figure 1: ϕ_{+-} vs Δm for experiments which do not assume CPT invariance. Δm measurements appear as vertical bands spanning $\Delta m \pm 1\sigma$, cut near the top and bottom to aid the eye. Most ϕ_{+-} measurements appear as diagonal bands spanning $\phi_{+-} \pm \sigma_\phi$. Data are labeled by letters: "b"–FNAL KTeV, "c"–CERN CPLEAR, "d"–FNAL E773, "e"–FNAL E731, "f"–CERN, "g"–CERN NA31, and are cited in Table 1. The narrow band "j" shows ϕ_{SW}. The ellipse "a" shows the $\chi^2 = 1$ contour of the fit result. See full-color version on color pages at end of book.

The data on τ_S, Δm, and ϕ_{+-} shown in Figs. [1] and [2]. are combined with data on ϕ_{00} and $\phi_{00} - \phi_{+-}$ in two fits, one without assuming CPT and the other with this assumption. The results without assuming CPT are shown as ellipses labeled "a". These ellipses are seen to be in good agreement with the superweak phase

$$\phi_{SW} = \tan^{-1}\left(\frac{2\Delta m}{\Delta\Gamma}\right) = \tan^{-1}\left(\frac{2\Delta m \tau_S \tau_L}{\hbar(\tau_L - \tau_S)}\right) . \qquad (9)$$

In Figs. [1] and [2], ϕ_{SW} is shown as narrow bands labeled "j".

Table 1: References, Document ID's, and sources corresponding to the letter labels in the figures. The data are given in the ϕ_{+-} and Δm sections of the K_L Particle Listings, and the τ_S section of the K_S Particle Listings.

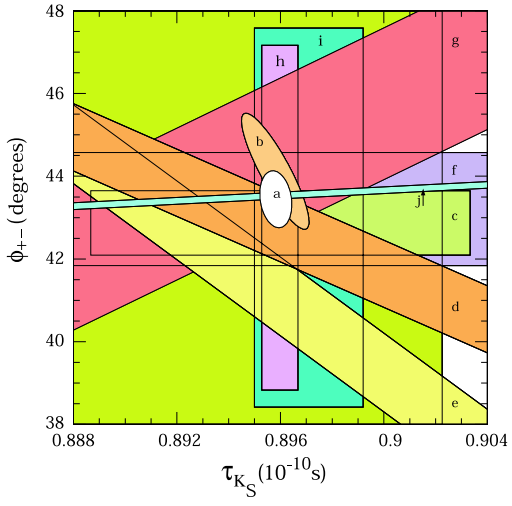

Figure 2: ϕ_{+-} vs τ_S. τ_S measurements appear as vertical bands spanning $\tau_S \pm 1\sigma$, some of which are cut near the top and bottom to aid the eye. Most ϕ_{+-} measurements appear as diagonal or horizontal bands spanning $\phi_{+-} \pm \sigma_\phi$. Data are labeled by letters: "b"–FNAL KTeV, "c"–CERN CPLEAR, "d"–FNAL E773, "e"–FNAL E731, "f"–CERN, "g"–CERN NA31, "h"–CERN NA48, "i"–CERN NA31, and are cited in Table 1. The narrow band "j" shows ϕ_{SW}. The ellipse "a" shows the fit result's $\chi^2 = 1$ contour. Color version at end of book.

Table 2 column 2, "Fit w/o CPT," gives the resulting fitted parameters, while Table 3 gives the correlation matrix for this fit. The white ellipses labeled "a" in Fig. 1 and Fig. 2 are the $\chi^2 = 1$ contours for this fit.

For experiments which have dependencies on unseen fit parameters, that is, parameters other than those shown on the x or y axis of the figure, their band positions are evaluated using the fit results and their band widths include the fitted uncertainty in the unseen parameters. This is also true for the $\phi_{\rm SW}$ bands.

If CPT invariance and unitarity are assumed, then by Eq. (6a), the phase of ϵ is constrained to be approximately equal to

$$\phi_{\rm SW} = (43.507 \pm 0.0004)^\circ + 54(\Delta m = 0.5290)^\circ + 32(\tau_S - 0.8958) \quad (10)$$

where we have linearized the Δm and τ_S dependence of Eq. (9). The error ± 0.0004 is due to the uncertainty in τ_L. Here Δm has units $10^{10}\,\hbar\,{\rm s}^{-1}$ and τ_S has units 10^{-10} s.

If in addition we use the observation that $Re(\epsilon'/\epsilon) \ll 1$ and $cos(\phi_{\epsilon'} - \phi_\epsilon) \simeq 1$, as well as the numerical value of $\phi_{\epsilon'} - \phi_\epsilon$ given in Eq. (6b), then Eqs. (5a), which are sketched in Fig. 3, lead to the constraint

$$\begin{aligned} \phi_{00} - \phi_{+-} &\approx -3\ {\rm Im}\left(\frac{\epsilon'}{\epsilon}\right) \\ &\approx -3\ {\rm Re}\left(\frac{\epsilon'}{\epsilon}\right) \tan(\phi_{\epsilon'} - \phi_\epsilon) \\ &\approx -0.023^\circ \pm 0.020^\circ \end{aligned} \quad (11)$$

so that $\phi_{+-} \approx \phi_{00} \approx \phi_\epsilon \approx \phi_{\rm SW}$.

In the fit assuming CPT we constrain $\phi_\epsilon = \phi_{\rm SW}$ using the linear expression in Eq. (10) and constrain $\phi_{00} - \phi_{+-}$ using Eq. (11). These constraints are inserted into the Data Listings with the Document ID of SUPERWEAK 04. Some additional data for which the authors assumed CPT are added to this fit or substitute for other less precise data for which the authors did not make this assumption. See the data listings for details.

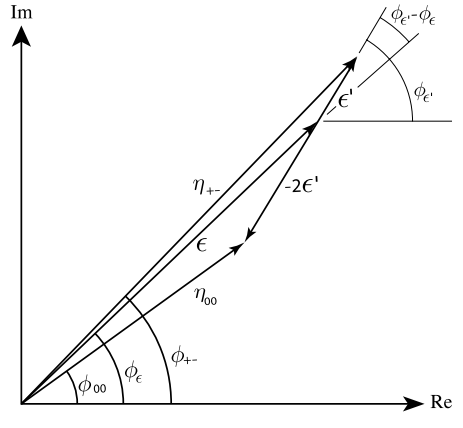

Figure 3: Sketch of Eqs. (5a). Not to scale.

The results of this fit are shown in Table 2, column 3, "Fit w/CPT," and the correlation matrix is shown in Table 4. The Δm precision is improved by the CPT assumption.

Table 2: Fit results for ϕ_{+-}, Δm, τ_S, ϕ_{00}, $\Delta\phi = \phi_{00} - \phi_{+-}$, and ϕ_ϵ without and with the CPT assumption.

Fits for ϵ'/ϵ, $|\eta_{+-}|$, $|\eta_{00}|$, and B($K_L \to \pi\pi$)

We list measurements of $|\eta_{+-}|$, $|\eta_{00}|$, $|\eta_{00}/\eta_{+-}|$ and ϵ'/ϵ. Independent information on $|\eta_{+-}|$ and $|\eta_{00}|$ can be obtained from measurements of the K^0_L and K^0_S lifetimes (τ_L, τ_S) and branching ratios (B) to $\pi\pi$, using the relations

$$|\eta_{+-}| = \left[\frac{{\rm B}(K^0_L \to \pi^+\pi^-)}{\tau_L}\ \frac{\tau_S}{{\rm B}(K^0_S \to \pi^+\pi^-)}\right]^{1/2}, \quad (12a)$$

$$|\eta_{00}| = \left[\frac{{\rm B}(K^0_L \to \pi^0\pi^0)}{\tau_L}\ \frac{\tau_S}{{\rm B}(K^0_S \to \pi^0\pi^0)}\right]^{1/2}. \quad (12b)$$

For historical reasons the branching ratio fits and the CP-violation fits are done separately, but we want to include the influence of $|\eta_{+-}|$, $|\eta_{00}|$, $|\eta_{00}/\eta_{+-}|$, and ϵ'/ϵ measurements on $B(K^0_L \to \pi^+\pi^-)$ and $B(K^0_L \to \pi^0\pi^0)$ and vice versa. We approximate a global fit to all of these measurements by first performing two independent fits: 1) BRFIT, a fit to the K^0_L branching ratios, rates, and mean life, and 2) ETAFIT, a fit to the $|\eta_{+-}|$, $|\eta_{00}|$, $|\eta_{+-}/\eta_{00}|$, and ϵ'/ϵ measurements. The results from fit 1, along with the K^0_S values from this edition are used to compute values of $|\eta_{+-}|$ and $|\eta_{00}|$ which are included as measurements in the $|\eta_{00}|$ and $|\eta_{+-}|$ sections with a document ID of BRFIT 04. Thus the fit values of $|\eta_{+-}|$ and $|\eta_{00}|$ given in this edition include both the direct measurements and the results from the branching ratio fit.

The process is reversed in order to include the direct $|\eta|$ measurements in the branching ratio fit. The results from fit 2 above (before including BRFIT 04 values) are used along with the K^0_L and K^0_S mean lives and the $K^0_S \to \pi\pi$ branching fractions to compute the K^0_L branching ratios $\Gamma(K^0_L \to \pi^+\pi^-)/\Gamma(\text{total})$ and $\Gamma(K^0_L \to \pi^0\pi^0)/\Gamma(K^0_L \to \pi^+\pi^-)$. These branching ratio values are included as measurements in the branching ratio section with a document ID of ETAFIT 04. Thus the K^0_L branching ratio fit values in this edition include the results of direct measurements of $|\eta_{+-}|$, $|\eta_{00}|$, $|\eta_{00}/\eta_{+-}|$, and ϵ'/ϵ. A more detailed discussion of these fits is given in the 1990 edition of this *Review* [18].

CP-VIOLATION PARAMETERS IN K^0_L DECAYS

CHARGE ASYMMETRY IN $K^0_{\ell 3}$ DECAYS

Such asymmetry violates CP. It is related to $\mathrm{Re}(\epsilon)$.

δ_L = weighted average of $\delta_L(\mu)$ and $\delta_L(e)$

PARAMETERS FOR $K^0_L \to 2\pi$ DECAY

$\eta_{+-} = A(K^0_L \to \pi^+\pi^-) / A(K^0_S \to \pi^+\pi^-)$

$\eta_{00} = A(K^0_L \to \pi^0\pi^0) / A(K^0_S \to \pi^0\pi^0)$

The fitted values of $|\eta_{+-}|$ and $|\eta_{00}|$ given below are the results of a fit to $|\eta_{+-}|$, $|\eta_{00}|$, $|\eta_{00}/\eta_{+-}|$, and $\mathrm{Re}(\epsilon'/\epsilon)$. Independent information on $|\eta_{+-}|$ and $|\eta_{00}|$ can be obtained from the fitted values of the $K^0_L \to \pi\pi$ and $K^0_S \to \pi\pi$ branching ratios and the K^0_L and K^0_S lifetimes. This information is included as data in the $|\eta_{+-}|$ and $|\eta_{00}|$ sections with a Document ID "BRFIT." See the note "CP violation in K_L decays" above for details.

$|\eta_{00}| = |A(K^0_L \to 2\pi^0) / A(K^0_S \to 2\pi^0)|$

2.95 ± 0.63	[85] CHOLLET	70	OSPK	Cu reg., 4γ's

[84] Error is statistical only.

[85] CHOLLET 70 gives $|\eta_{00}| = (1.23 \pm 0.24)\times$(regeneration amplitude, 2 GeV/c Cu)/10000mb. WOLFF 71 gives $|\eta_{00}| = (1.13 \pm 0.12)\times$(regeneration amplitude, 2 GeV/c Cu)/10000mb. We compute both $|\eta_{00}|$ values for (regeneration amplitude, 2 GeV/c Cu) = 24 ± 2mb. This regeneration amplitude results from averaging over FAISSNER 69, extrapolated using optical-model calculations of Bohm et al., Physics Letters **27B** 594 (1968) and the data of BALATS 71. (From H. Faissner, private communication).

$|\eta_{+-}| = |A(K^0_L \to \pi^+\pi^-) / A(K^0_S \to \pi^+\pi^-)|$

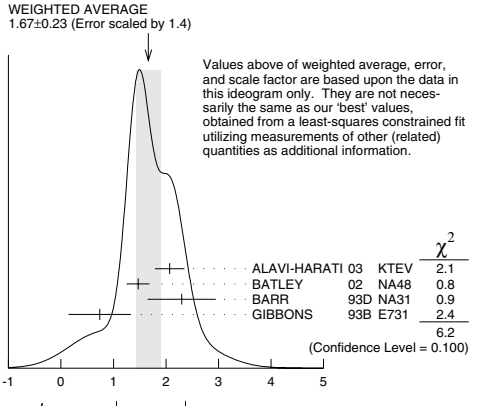
[91] These values are derived from $|\eta_{00}/\eta_{+-}|$ measurements. They enter the average in this section but enter the fit via the $|\eta_{00}/\eta_{+-}|$ only.

[92] This is the combined results from BARR 93D and BURKHARDT 88, taking into account their common systematic uncertainty.

[93] These values are derived from $|\eta_{00}/\eta_{+-}|$ measurements.



$\mathrm{Re}(\epsilon'/\epsilon) = (1 - |\eta_{00}/\eta_{+-}|)/3$

ϕ_{+-}, PHASE of η_{+-}

The dependence of the phase on Δm and τ_S is given for each experiment in the comments below, where Δm is the $K^0_L - K^0_S$ mass difference in units 10^{10} $\hbar s^{-1}$ and τ_S is the K_S mean life in units 10^{-10} s. We also give the regeneration phase ϕ_f in the comments below.

OUR FIT is described in the note on "CP violation in K_L decays" in the K^0_L Particle Listings. Most experiments in this section are included in both the "Not Assuming CPT" and "Assuming CPT" fits. In the latter fit, they have little direct influence on ϕ_{+-} because their errors are large compared to that assuming CPT, but they influence Δm and τ_S through their dependencies on these parameters, which are given in the footnotes. Only ALAVI-HARATI 03 is excluded from the "Assuming CPT" fit because we explicitly include their Δm and τ_S measurements which assume CPT.

44.3 ±2.8 ±0.2		[106] CARITHERS	75	SPEC	C regenerator

[94] ALAVI-HARATI 03 ϕ_{+-} is correlated with their $\Delta m = m_{K^0_L} - m_{K^0_S}$ and τ_{K_S} measurements in the K^0_L and K^0_S sections respectively. The correlation coefficients are $\rho(\phi_{+-}, \Delta m) = +0.955$, $\rho(\phi_{+-}, \tau_S) = -0.871$, and $\rho(\tau_S, \Delta m) = -0.840$. CPT is not assumed. Uses scintillator Pb regenerator.

[95] APOSTOLAKIS 99C measures $\phi_{+-} = (43.19 \pm 0.53 \pm 0.28) + 300\,[\Delta m - 0.5301]$ (°). We have adjusted the measurement to use our best values of $(\Delta m = 0.5292 \pm 0.0010)$ $(10^{10}\ \hbar\ s^{-1})$. Our first error is their experiment's error and our second error is the systematic error from using our best values.

[96] SCHWINGENHEUER 95 measures $\phi_{+-} = (43.53 \pm 0.76) + 173\,[\Delta m - 0.5282] - 275\,[\tau_S - 0.8926]$ (°). We have adjusted the measurement to use our best values of $(\Delta m = 0.5292 \pm 0.0010)$ $(10^{10}\ \hbar\ s^{-1})$, $(\tau_S = 0.8953 \pm 0.0006)$ $(10^{-10}$ s). Our first error is their experiment's error and our second error is the systematic error from using our best values.

[97] These experiments measure $\phi_{+-} - \phi_f$ and calculate the regeneration phase from the power law momentum dependence of the regeneration amplitude using analyticity and dispersion relations. SCHWINGENHEUER 95 [GIBBONS 93] includes a systematic error of 0.35° [0.5°] for uncertainties in their modeling of the regeneration amplitude. See the discussion of these systematic errors, including criticism that they could be underestimated, in the note on "C violation in K^0_L decay."

[98] GIBBONS 93 measures $\phi_{+-} = (42.21 \pm 0.9) + 189\,[\Delta m - 0.5257] - 460\,[\tau_S - 0.8922]$ (°). We have adjusted the measurement to use our best values of $(\Delta m = 0.5292 \pm 0.0010)$ $(10^{10}\ \hbar\ s^{-1})$, $(\tau_S = 0.8953 \pm 0.0006)$ $(10^{-10}$ s). Our first error is their experiment's error and our second error is the systematic error from using our best values. This is actually reported in SCHWINGENHEUER 95, footnote 8. GIBBONS 93 reports $\phi_{+-} = (42.2 \pm 1.4)°$. They measure $\phi_{+-} - \phi_f$ and calculate the regeneration phase ϕ_f from the power law momentum dependence of the regeneration amplitude using analyticity. An error of 0.6° is included for possible uncertainties in the regeneration phase.

[99] CAROSI 90 measures $\phi_{+-} = (46.9 \pm 1.4 \pm 0.7) + 579\,[\Delta m - 0.5351] + 303\,[\tau_S - 0.8922]$ (°). We have adjusted the measurement to use our best values of $(\Delta m = 0.5292 \pm 0.0010)$ $(10^{10}\ \hbar\ s^{-1})$, $(\tau_S = 0.8953 \pm 0.0006)$ $(10^{-10}$ s). Our first error is their experiment's error and our second error is the systematic error from using our best values.

[100] GEWENIGER 74B measures $\phi_{+-} = (49.4 \pm 1.0) + 565\,[\Delta m - 0.540]$ (°). We have adjusted the measurement to use our best values of $(\Delta m = 0.5292 \pm 0.0010)$ $(10^{10}\ \hbar\ s^{-1})$. Our first error is their experiment's error and our second error is the systematic error from using our best values.

[101] ADLER 96C measures $\phi_{+-} = (43.82 \pm 0.41) + 339\,[\Delta m - 0.5307] - 252\,[\tau_S - 0.8922]$ (°). We have adjusted the measurement to use our best values of $(\Delta m = 0.5292 \pm 0.0010)$ $(10^{10}\ \hbar\ s^{-1})$, $(\tau_S = 0.8953 \pm 0.0006)$ $(10^{-10}$ s). Our first error is their experiment's error and our second error is the systematic error from using our best values.

[102] ADLER 96C is the result of a fit which includes nearly the same data as entered into the "OUR FIT" value in the 1996 edition of this Review (Physical Review **D54** 1 (1996)).

[103] ADLER 95B measures $\phi_{+-} = (42.7 \pm 0.9 \pm 0.6) + 316\,[\Delta m - 0.5274] + 30\,[\tau_S - 0.8926]$ (°). We have adjusted the measurement to use our best values of $(\Delta m = 0.5292 \pm 0.0010)$ $(10^{10}\ \hbar\ s^{-1})$, $(\tau_S = 0.8953 \pm 0.0006)$ $(10^{-10}$ s). Our first error is their experiment's error and our second error is the systematic error from using our best values.

[104] ADLER 92B quote separately two systematic errors: ±0.4 from their experiment and ±1.0 degrees due to the uncertainty in the value of Δm.

[105] KARLSSON 90 systematic error does not include regeneration phase uncertainty.

[106] CARITHERS 75 measures $\phi_{+-} = (45.5 \pm 2.8) + 224\,[\Delta m - 0.5348]$ (°). We have adjusted the measurement to use our best values of $(\Delta m = 0.5292 \pm 0.0010)$ $(10^{10}\ \hbar\ s^{-1})$. Our first error is their experiment's error and our second error is the systematic error from using our best values. $\phi_f = -40.9 \pm 2.6°$.

ϕ_{00}, PHASE OF η_{00}

See comment in ϕ_{+-} header above for treatment of Δm and τ_S dependence, as well as for the inclusion of data in both the "Assuming *CPT*" and "Not Assuming *CPT*" fits.

OUR FIT is described in the note on "*CP* violation in K_L decays" in the K^0_L Particle Listings.

VALUE (°)	DOCUMENT ID		TECN	COMMENT
43.50±0.06 OUR FIT	Error includes scale factor of 1.3.			Assuming *CPT*
43.7 ±0.8 OUR FIT	Error includes scale factor of 1.2.			Not assuming *CPT*
44.5 ±2.3 ±0.6	[107] CAROSI	90	NA31	
• • • We do not use the following data for averages, fits, limits, etc. • • •				
41.6 ±5.9 ±0.2	[108] ANGELOPO...	98	CPLR	
50.8 ±7.1 ±1.7	[109] ADLER	96B	CPLR	Sup. by ANGELOPOULOS 98
47.4 ±1.4 ±0.9	[110] KARLSSON	90	E731	

[107] CAROSI 90 measures $\phi_{00} = (47.1 \pm 2.1 \pm 1.0) + 579\,[\Delta m - 0.5351] + 252\,[\tau_S - 0.8922]$ (°). We have adjusted the measurement to use our best values of ($\Delta m = 0.5292 \pm 0.0010$) ($10^{10}\ \hbar\ s^{-1}$), ($\tau_S = 0.8953 \pm 0.0006$) ($10^{-10}$ s). Our first error is their experiment's error and our second error is the systematic error from using our best values.

[108] ANGELOPOULOS 98 measures $\phi_{00} = (42.0 \pm 5.6 \pm 1.9) + 240\,[\Delta m - 0.5307]$ (°). We have adjusted the measurement to use our best values of ($\Delta m = 0.5292 \pm 0.0010$) ($10^{10}\ \hbar\ s^{-1}$). Our first error is their experiment's error and our second error is the systematic error from using our best values. The τ_S dependence is negligible.

[109] ADLER 96B identified initial neutral kaon individually as being a K^0 or a $\overline{K}{}^0$. The systematic uncertainty is $\pm 1.5°$ combined in quadrature with $\pm 0.8°$ due to Δm.

[110] KARLSSON 90 systematic error does not include regeneration phase uncertainty.

$\phi_\epsilon = (2\phi_{+-} + \phi_{00})/3$

This expression is a very good approximation, good to about 10^{-3} degrees because of the small measured values of $\phi_{00} - \phi_{+-}$ and Re ϵ'/ϵ, and small theoretical ambiguities.

VALUE (°)	DOCUMENT ID		COMMENT
43.51 ±0.05 OUR FIT	Error includes scale factor of 1.2. Assuming *CPT*		
43.5 ±0.7 OUR FIT	Error includes scale factor of 1.3. Not assuming *CPT*		
43.5105±0.0004±0.0548	[111] SUPERWEAK	04	Assuming *CPT*

[111] SUPERWEAK 04 is a fake measurement used to impose the *CPT* or Superweak constraint $\phi_{+-} = \phi_{SW} = 2\,\frac{\Delta m}{\hbar}\,(\frac{\tau_S \tau_L}{\tau_L - \tau_S})$. This "measurement" is linearized using values near the RPP 2004 edition values of Δm, τ_S and τ_L, and then adjusted to our current values as described in the following "measurement". SUPERWEAK 04 measures $\phi_\epsilon = (43.5131 \pm 0.0004) + 54\,[\Delta m - 0.5290] + 32\,[\tau_S - 0.8958]$ (°). We have adjusted the measurement to use our best values of ($\Delta m = 0.5292 \pm 0.0010$) ($10^{10}\ \hbar\ s^{-1}$), ($\tau_S = 0.8953 \pm 0.0006$) ($10^{-10}$ s). Our first error is their experiment's error and our second error is the systematic error from using our best values.

DECAY-PLANE ASYMMETRY IN $\pi^+\pi^-e^+e^-$ DECAYS

This is the *CP*-violating asymmetry

$$A = \frac{N_{\sin\phi\cos\phi>0.0} - N_{\sin\phi\cos\phi<0.0}}{N_{\sin\phi\cos\phi>0.0} + N_{\sin\phi\cos\phi<0.0}}$$

where ϕ is the angle between the e^+e^- and $\pi^+\pi^-$ planes in the K^0_L rest frame.

PARAMETERS FOR $e^+e^-e^+e^-$ DECAYS

These are the *CP*-violating parameters in the ϕ distribution, where ϕ is the angle between the planes of the two e^+e^- paris in the kaon rest frame:

$$d\Gamma/d\phi \propto 1 + \beta_{CP}\cos(2\phi) + \gamma_{CP}\sin(2\phi)$$

β_{CP} from $K^0_L \to e^+e^-e^+e^-$

−0.023±0.020	[115] SUPERWEAK	04		Assuming *CPT*
0.39 ±0.22 ±0.45	[116] ALAVI-HARATI	03	KTEV	
−0.30 ±0.88	[117] SCHWINGEN...	95		Combined E731, E773
• • • We do not use the following data for averages, fits, limits, etc. • • •				
0.62 ±0.71 ±0.75	SCHWINGEN...	95	E773	
−1.6 ±1.2	[118] GIBBONS	93	E731	
0.2 ±2.6 ±1.2	[119] CAROSI	90	NA31	
−0.3 ±2.4 ±1.2	KARLSSON	90	E731	

[115] SUPERWEAK 04 is a fake experiment to constrain ϕ_{00}-ϕ_{+-} to a small value as described in the note "*CP* violation in K_L decays."

[116] ALAVI-HARATI 03 fit Re(ϵ'/ϵ), Im(ϵ'/ϵ), Δm, τ_S, and ϕ_{+-} simultaneously, not assuming *CPT*. Phase difference is obtained from $\phi_{00} - \phi_{+-} \approx -3\,\mathrm{Im}(\epsilon'/\epsilon)$ for small $|\epsilon'/\epsilon|$.

[117] This SCHWINGENHEUER 95 values is the combined result of SCHWINGENHEUER 95 and GIBBONS 93, accounting for correlated systematic errors.

[118] GIBBONS 93 give detailed dependence of systematic error on lifetime (see the section on the K^0_S mean life) and mass difference (see the section on $m_{K^0_L} - m_{K^0_S}$).

[119] CAROSI 90 is excluded from the fit because it it is not independent of ϕ_{+-} and ϕ_{00} values.

PHASE DIFFERENCE $\phi_{+-} - \phi_{SW}$

Test of *CPT*. The Superweak phase $\phi_{SW} \equiv \tan^{-1}(2\Delta m/\Delta\Gamma)$ where $\Delta m = m_{K^0_L} - m_{K^0_S}$ and $\Delta\Gamma = \hbar(\tau_L - \tau_S)/(\tau_L \tau_S)$.

VALUE (°)	DOCUMENT ID		TECN
0.61±0.62±1.01	[120] ALAVI-HARATI	03	KTEV

[120] ALAVI-HARATI 03 fit is the same as their ϕ_{+-}, τ_{K_S}, Δm fit, except that the parameter $\phi_{+-} - \phi_{SW}$ is used in place of ϕ.

$\mathrm{Re}(\frac{2}{3}\eta_{+-} + \frac{1}{3}\eta_{00}) - \frac{\delta_L}{2}$
Test of CPT

VALUE (units 10^{-6})	DOCUMENT ID		TECN	COMMENT
-3 ± 35	[121] ALAVI-HARATI 02		E799	Uses δ_L from K_{e3} decays

[121] ALAVI-HARATI 02 uses PDG 00 values of η_{+-} and η_{00}.

$\Delta S = \Delta Q$ IN K^0 DECAYS

The relative amount of $\Delta S \neq \Delta Q$ component present is measured by the parameter x, defined as

$$x = A(\overline{K}^0 \to \pi^- \ell^+ \nu)/A(K^0 \to \pi^- \ell^+ \nu) \ .$$

We list $\mathrm{Re}\{x\}$ and $\mathrm{Im}\{x\}$ for K_{e3} and $K_{\mu 3}$ combined.

$x = A(\overline{K}^0 \to \pi^- \ell^+ \nu)/A(K^0 \to \pi^- \ell^+ \nu) = A(\Delta S = -\Delta Q)/A(\Delta S = \Delta Q)$

$K^*(892)$ MASSES AND MASS DIFFERENCES

Unrealistically small errors have been reported by some experiments. We use simple "realistic" tests for the minimum errors on the determination of a mass and width from a sample of N events:

$$\delta_{\min}(m) = \frac{\Gamma}{\sqrt{N}}, \quad \delta_{\min}(\Gamma) = 4\frac{\Gamma}{\sqrt{N}}\ . \tag{1}$$

We consistently increase unrealistic errors before averaging. For a detailed discussion, see the 1971 edition of this Note.

CONSTRAINED FIT INFORMATION

An overall fit to the total width and a partial width uses 13 measurements and one constraint to determine 3 parameters. The overall fit has a $\chi^2 = 7.8$ for 11 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \cdot \delta p_j)$, in percent, from the fit to parameters p_i, including the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

CONSTRAINED FIT INFORMATION

An overall fit to the total width, a partial width, and 10 branching ratios uses 31 measurements and one constraint to determine 8 parameters. The overall fit has a $\chi^2 = 20.2$ for 24 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle\delta p_i \delta p_j\rangle/(\delta p_i \cdot \delta p_j)$, in percent, from the fit to parameters p_i, including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

CONSTRAINED FIT INFORMATION

An overall fit to 4 branching ratios uses 4 measurements and one constraint to determine 3 parameters. The overall fit has a $\chi^2 = 2.9$ for 2 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$K_2(1770)$

$I(J^P) = \frac{1}{2}(2^-)$

THE $K_2(1770)$ AND THE $K_2(1820)$

A partial-wave analysis of the $K^-\omega$ system based on about 100,000 $K^-p \to K^-\omega p$ events (ASTON 93) gives evidence for two $q\bar{q}$ D-wave states near 1.8 GeV. A previous analysis based on about 200,000 diffractively produced $K^-p \to K^-\pi^+\pi^-p$ events (DAUM 81) gave evidence for two $J^P = 2^-$ states in this region, with masses $\sim$ 1780 MeV and $\sim$ 1840 MeV and widths $\sim$ 200 MeV, in good agreement with the results of ASTON 93. In contrast, the masses obtained using a single resonance do not agree well: ASTON 93 obtains 1728 ± 7 MeV, while DAUM 81 estimates $\sim$ 1820 MeV. We conclude that there are indeed two K_2 resonances here.

We list under the $K_2(1770)$ other measurements that do not resolve the two-resonance structure of the enhancement.

References

References may be found at the end of the $K_2(1770)$ Listing.

CONSTRAINED FIT INFORMATION

An overall fit to 3 branching ratios uses 4 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2 = 0.0$ for 1 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$K(3100)$

$I^G(J^{PC}) = ?^?(?^{??})$

OMITTED FROM SUMMARY TABLE

Narrow peak observed in several ($\Lambda\overline{p}$ + pions) and ($\overline{\Lambda}p$ + pions) states in Σ^- Be reactions by BOURQUIN 86 and in np and nA reactions by ALEEV 93. Not seen by BOEHNLEIN 91. If due to strong decays, this state has exotic quantum numbers (B=0,Q=+1,S=−1 for $\Lambda\overline{p}\pi^+\pi^+$ and $I \geq 3/2$ for $\Lambda\overline{p}\pi^-$). Needs confirmation.

Γ_{178} A dummy mode used by the fit. (31 ± 5) %

[a] This is a weighted average of $D^{\pm}$ (44%) and D^0 (56%) branching fractions. See "D^+ and $D^0 \to$ (η anything) / (total D^+ and D^0)" under "D^+ Branching Ratios" in these Particle Listings.

[b] This value averages the e^+ and μ^+ branching fractions, after making a small phase-space adjustment to the μ^+ fraction to be able to use it as an e^+ fraction; hence our ℓ^+ here is really an e^+.

[c] An ℓ indicates an e or a μ mode, not a sum over these modes.

[d] The branching fraction for this mode may differ from the sum of the submodes that contribute to it, due to interference effects. See the relevant papers.

[e] The two experiments measuring this fraction are in serious disagreement. See the Particle Listings.

[f] This value includes only $\pi^+\pi^-$ decays of the intermediate resonance, because branching fractions of this resonance are not known.

[g] Unseen decay modes of the resonance are included.

[h] This mode is not a useful test for a $\Delta C=1$ weak neutral current because both quarks must change flavor in this decay.

[i] The value is for the sum of the charge states or particle/antiparticle states indicated.

CONSTRAINED FIT INFORMATION

An overall fit to 33 branching ratios uses 58 measurements and one constraint to determine 20 parameters. The overall fit has a $\chi^2 = 47.9$ for 39 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\rm total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

[39] PERUZZI 77 (MARK-1) measures $\sigma(e^+e^- \to \psi(3770)) \times$ branching fraction to be 0.14 ± 0.05 nb. We use the MARK-3 (ADLER 88C) value of $\sigma = 4.2 \pm 0.6 \pm 0.3$ nb.

$\Gamma(\overline{K}^0\pi^+)/\Gamma(K^-\pi^+\pi^+)$ Γ_{38}/Γ_{39}

It is generally assumed for modes such as $D^+ \to \overline{K}^0\pi^+$ that
$\Gamma(D^+ \to \overline{K}^0\pi^+) = 2\Gamma(D^+ \to K^0_S\pi^+)$;
it is the latter Γ that is actually measured. BIGI 95 points out that interference between Cabibbo-allowed and doubly Cabibbo-suppressed amplitudes, where both occur, could invalidate this assumption by a few percent.

REVIEW OF CHARM DALITZ-PLOT ANALYSES

Written November 2003 by D. Asner (University of Pittsburgh)

Weak nonleptonic decays of charm mesons are expected to proceed dominantly through resonant two-body decays in several theoretical models [1]. The Dalitz-plot analysis technique [2,3] has been applied to the decays $D \to rc$, $r \to ab$ where the decay products a, b, and c are K or π and the intermediate state r is a scalar, vector, or tensor meson. Table 1 lists published analyses of $D \to \overline{K}\pi\pi$, $\to \pi\pi\pi$, $\to \overline{K}K\pi$, and $\to \overline{K}K\overline{K}$ decays. The analyses include studies of doubly Cabibbo-suppressed decays [4,5], searches for CP violation [5–8], properties of established light mesons [9–11], and properties of $\pi\pi$ [4,11,12] and $K\pi$ [13] S-wave states. Future studies could improve sensitivity to D^0–$\overline{D}^0$ mixing [14].

The amplitude of the process, $D \to rc, r \to ab$, is given by the product of three factors: the angular distributions [15,16] of final-state particles, the barrier form factors [17,18] for the production of rc and ab, respectively, and the dynamical function describing the resonance r. Usually r is modeled with a Breit-Wigner, and the nonresonant contribution is parameterized as an S-wave with no variation in magnitude or phase across the Dalitz plot. Some more recent analyses have used the K-matrix formalism [19] with the P-vector approximation [20] to describe the $\pi\pi$ S-wave.

In the following, we discuss a number of subjects of current interest.

Table 1: Reported Dalitz Plot Analyses.

Decay	Experiment(s)

$D^+_s \to \pi^+\pi^+\pi^-$	E687 [9], E791 [10], FOCUS [11]

$D^0 \to K^0_S\pi^+\pi^-$ — Several experiments have analyzed the decay $D^0 \to K^0_S\pi^+\pi^-$. The earliest analyses, by Mark II [21], Mark III [22], and E687 [23], assumed only two intermediate resonances, $K^0_S\rho^0$, $K^*(892)^-\pi^+$, and a significant nonresonant component. Additional resonances were considered by E691 [24] but were not found to be statistically significant. ARGUS [25] and E687 [26], with more events, fit the Dalitz plot with six intermediate resonances: $K^*(892)^-\pi^+$, $K^*_0(1430)^-\pi^+$, $K^0_S\rho^0$, $K^0_Sf_0(975)$, $K^0_Sf_2(1270)$, and $K^0_Sf_0(1400)$. The nonresonant contribution was negligible. The early and later E687 results [23, 26] were consistent under similar assumptions. The most precise results are from CLEO [4], which includes three additional resonances: $K^0_S\omega, K^*(1680)^-\pi^+$ and the doubly Cabibbo-suppressed $K^*(892)^+\pi^-$. They find a much smaller nonresonant contribution than did the earliest experiments.

It is not straightforward to compare or combine results using different descriptions of the angular distributions, barrier factors, resonant parametrizations, and different sets of resonances. Some of the earlier results [22–24], did not include barrier factors [17, 18]. Most of the earlier results [22–24, 26] used the Zemach formalism [15] to describe the angular shape of the decay pattern, while the more recent results [25, 4] use the helicity formalism [16].

The significance of the nonresonant component in the smaller data samples has been attributed to the presence of the broad scalar resonances $K_0^*(1430)^-$ and $f_0(1370)$ that were later observed in the larger data samples. The observation of a small but significant nonresonant component in the largest data samples suggests the presence of additional broad scalar resonances, the $\kappa(800)$ and $\sigma(500)$. The CLEO analysis could accomodate the $\sigma(500)$ in lieu of the nonresonant component, but found no evidence for the $\kappa(800)$.

$D^0 \to \pi^+\pi^-\pi^0$ and $D^0 \to \overline{K}^0 K^+ K^-$ — The only significant contribution to the resonant substructure of $D^0 \to \pi^+\pi^-\pi^0$ is in the $\rho\pi$ channels. A small nonresonant component is observed but all other $\pi\pi$ resonances, including the $\sigma(500)$, yielded fit fractions consistent with zero. The CLEO [8] results for $D^0 \to \pi^+\pi^-\pi^0$ are given in Table 2.

Table 2: Dalitz fit results of $D^0 \to \pi^+\pi^-\pi^0$.

Resonance	Amplitude	Phase(°)	Fit fraction(%)
ρ^+	1. (fixed)	0. (fixed)	$76.5 \pm 1.8 \pm 4.8$
ρ^0	$0.56 \pm 0.02 \pm 0.07$	$10 \pm 3 \pm 3$	$23.9 \pm 1.8 \pm 4.6$
ρ^-	$0.65 \pm 0.03 \pm 0.04$	$-4 \pm 3 \pm 4$	$32.3 \pm 2.1 \pm 2.2$
nonresonant	$1.03 \pm 0.17 \pm 0.31$	$77 \pm 8 \pm 11$	$2.7 \pm 0.9 \pm 1.7$

The BABAR [27] results for $D^0 \to \overline{K}^0 K^+ K^-$ are given in Table 3. The non-ϕ resonant substructure in K^+K^- is significant. Resonant contributions from $a_0(980)^0$, $a_0(980)^+$, and $f_0(980)$ are observed. The nonresonant and the doubly Cabibbo-suppressed contributions are consistent with zero.

Table 3: Dalitz fit results of $D^0 \to \overline{K}^0 K^+ K^-$.

Resonance	Phase(°)	Fit fraction(%)
$\overline{K}^0\phi$	0. (fixed)	$45.4 \pm 1.6 \pm 1.0$
$\overline{K}^0 a_0(980)$	109 ± 5	$60.9 \pm 7.5 \pm 13.3$
$\overline{K}^0 f_0(980)$	-161 ± 14	$12.2 \pm 3.1 \pm 8.6$
$a_0(980)^+ K^-$	-53 ± 4	$34.3 \pm 3.2 \pm 6.8$
$a_0(980)^- K^+$	-13 ± 15	$3.2 \pm 1.9 \pm 0.5$
nonresonant	40 ± 44	$0.4 \pm 0.3 \pm 0.8$

Charm Dalitz-plot analyses might be useful for calibrating tools used in B decays: specifically, to extract α from $B^0 \to \pi^+\pi^-\pi^0$, β from $B^0 \to \overline{K}^0 K^+ K^-$, and γ from $B^\pm \to DK^\pm$ followed by $D \to \overline{K}^0 K^+ K^-$ or $D \to \overline{K}^0 \pi^+\pi^-$ [28].

$D^+ \to \pi^+\pi^+\pi^-$: a $\sigma(500)$ or $f_0(600)$ — The decay $D^+ \to \pi^+\pi^+\pi^-$ has been studied by the E687 [9], E791 [12] and FOCUS [11] experiments. The E687 experiment considered the $\rho(770)^0\pi^+$, $f_0(980)\pi^+$, $f_2(1270)\pi^+$, and a nonresonant component. The E791 experiment included in addition $f_0(1370)\pi^+$ and $\rho(1450)^0\pi^+$. Both analyses found a very large fraction ($\sim 50\%$) for the nonresonant contribution, perhaps indicating a broad scalar contribution. E791 found the nonresonant amplitude to be consistent with zero if a broad scalar resonance was included in the fit. FOCUS analyzed its data sample using both the Breit-Wigner formalism and the K-matrix formalism. The Breit-Wigner analysis included $\rho(770), f_0(980), f_2(1270), f_0(1500), \sigma(500)$, and a nonresonant contribution. Applying the K-matrix formalism to the S wave and parameterizing the $\rho(770)$ and $f_2(1270)$ with the Breit-Wigner functions also described the FOCUS data well.

None of these analyses has modeled the dynamics of the $\pi^+\pi^+$ interaction. Consideration of the $I = 2$ S-wave and D-wave phase shifts, also measured in $\pi^+ p \to \pi^+\pi^+ n$ [31], could affect the $\pi^+\pi^-$ S-wave result.

E791 finds additional evidence that the low mass $\pi\pi$ feature is resonant by examining the phase of the $\pi\pi$ amplitude in the vicinity of the reported $\sigma(500)$ mass. A phase variation with invariant $\pi\pi$ mass is consistent with a resonant contribution [32].

Table 4 gives the parameters of the $\sigma(500)$ determined in charm Dalitz plot analyses. A consistent relative phase between the $\sigma(500)$ and $\rho(770)$ resonances is observed.

Table 4: Parameters of the $\sigma(500)$ resonance. The amplitude and phase are relative to the $\rho(770)$.

Experiment	E791 [12]	CLEO [4]	FOCUS [11]
Decay Mode	$D^+ \to \pi^+\pi^+\pi^-$	$D^0 \to K^0_S\pi^+\pi^-$	$D^+ \to \pi^+\pi^+\pi^-$
Amplitude	$1.17 \pm 0.13 \pm 0.06$	0.57 ± 0.13	—
Phase(°)	$205.7 \pm 8.0 \pm 5.2$	214 ± 11	200 ± 31
m(MeV/c^2)	$478^{+24}_{-23} \pm 17$	513 ± 32	443 ± 27
Γ(MeV/c^2)	$324^{+42}_{-40} \pm 21$	335 ± 67	443 ± 80

$D^+ \to K^-\pi^+\pi^+$: a $\kappa(800)$? — Indication of a broad $K\pi$ scalar intermediate resonance has been reported by E791 in the decay $D^+ \to K^-\pi^+\pi^+$ [13]. Fitting the Dalitz plot with $\overline{K}^*(892)^0\pi^+$, $\overline{K}^*_0(1430)^0\pi^+$, $\overline{K}^*_2(1430)^0\pi^+$, and $\overline{K}^*(1680)^0\pi^+$, plus a constant nonresonant component, E791 finds results consistent with earlier results from E691 and E687 with a nonresonant fit fraction of over 90%. Having reconstructed more events than the other experiments, E791 was led to include an extra low-mass S-wave $\overline{K}\pi$ resonance to account for the poor fit already seen by earlier experiments: A $\kappa(800)$ with $m = 797 \pm 19 \pm 43$ MeV/c^2 and $\Gamma = 410 \pm 43 \pm 87$ MeV/c^2 much improved the fits. The $\kappa(800)$ is now the dominant resonance and the nonresonant fit fraction is reduced from $90.9 \pm 2.6\%$ to $13.0 \pm 5.8 \pm 4.4\%$. As discussed with the $\sigma(500)$, the $K^-\pi^+$ S-wave result could be affected by modeling the dynamics of the $I = 2$ $\pi^+\pi^+$ interaction.

E791 also modeled the $K\pi$ S-wave phase variation as a function of $K\pi$ mass with the $K_0^*(1430)$ resonance only and a nonresonant component following the parameterization of LASS [33]. It was necessary to relax the unitarity constraint to describe the E791 data [34]. The $K\pi$ S-wave phase behavior in this model is consistent with the model that includes the κ resonance.

CLEO allowed scalar $K\pi$ resonances in the fit to $D^0 \to K^-\pi^+\pi^0$ [6] and $D^0 \to K^0_S\pi^+\pi^-$ [4] and observed a significant contribution for only $K^*_0(1430)$ [35]. BABAR has analyzed the decay $D^0 \to K^0K^-\pi^+$ and $D^0 \to \overline{K}^0K^+\pi^-$ [27]. They fit the former Dalitz plot with both positively charged and neutral $\overline{K}^*(892)$, $\overline{K}^*_0(1430)$, $\overline{K}^*_2(1430)$, $\overline{K}^*(1680)$ and $a_0(980)^-$, $a_0(1450)^-$, $a_2(1310)^-$ resonances, and a nonresonant component. The second Dalitz plot is fit with the identical resonances except for the $a_2(1310)^-$. A good fit is obtained in both cases without including the κ.

$f_0(980)$, $f_0(1370)$ and $f_0(1500)$ — The proximity of the $K\overline{K}$ threshold requires a coupled-channel or Flatte parametrization [36] of the $f_0(980)$ in charm Dalitz-plot analyses. The width of the $f_0(980)$ is poorly known. E791 used a coupled-channel Breit-Wigner function, following the parametrization of Ref. [37], to describe the $f_0(980)$ in $D^+_s \to \pi^+\pi^+\pi^-$ [10], and measured $m_r = 977 \pm 3 \pm 2$ MeV/c^2, $g_{\pi\pi} = 0.09 \pm 0.01 \pm 0.01$, and $g_{KK} = 0.02 \pm 0.04 \pm 0.03$. Results similar to these are desirable for input to the analysis of the $D^+_s \to K^+K^-\pi^+$ [29], which includes the $f_0(980)$ and $a_0(980)$.

The quark content of the $f_0(1370)$ and $f_0(1500)$ can perhaps be inferred from how they populate various Dalitz plots. The E791 analysis of $D^+ \to \pi^+\pi^+\pi^-$ [12] finds a contribution from the $f_0(1370)$ but not the $f_0(1500)$. The FOCUS analysis [11] of this decay does not find a significant contribution from the $f_0(1370)$. For the $D^+_s \to \pi^+\pi^+\pi^-$, E687 [9] and FOCUS [11] do not see the $f_0(1370)$ but do see a resonance with parameters similar to the $f_0(1500)$, while E791 [10] observes a $\pi\pi$ resonance ($m = 1434 \pm 18 \pm 9$ MeV/c^2 and $\Gamma = 172 \pm 32 \pm 6$ MeV/c^2) that is not consistent with either meson. BABAR has found no evidence for either the $f_0(1370)$ or the $f_0(1500)$ in $D^0 \to \overline{K}^0K^+K^-$ [27], while CLEO has observed the $f_0(1370)$ in $D^0 \to K^0_S\pi^+\pi^-$ [4]. Future analyses will present a clearer picture only if the same resonances and model of decay amplitudes are applied to all Dalitz-plot fits.

Doubly Cabibbo-Suppressed Decays — There are two classes of multibody doubly Cabibbo-suppressed (DCS) decays of charm mesons. The first consists of those in which the DCS and corresponding Cabbibo-favored (CF) decays populate distinct Dalitz plots: the pairs $D^0 \to K^+\pi^-\pi^0$ and $D^0 \to K^-\pi^+\pi^0$, or $D^+ \to K^+\pi^+\pi^-$ and $D^+ \to K^-\pi^+\pi^+$, are examples. CLEO [5] has reported $\dfrac{\mathcal{B}(D^0 \to K^+\pi^-\pi^0)}{\mathcal{B}(D^0 \to K^-\pi^+\pi^0)} = (0.43^{+0.11}_{-0.10} \pm 0.07)\%$.

The second class consists of decays where the DCS and CF modes populate the same Dalitz plot: for example, $D^0 \to K^{*-}\pi^+$ and $D^0 \to K^{*+}\pi^-$ both contribute to $D^0 \to K^0_S\pi^+\pi^-$. In this case, the potential for interference of DCS and CF amplitudes increases the sensitivity to the DCS amplitude. CLEO [4] has reported the relative amplitudes and phases to be $(7.1 \pm 1.3^{+2.6\,+2.6}_{-0.6\,-0.6})\%$ and $(189 \pm 10 \pm 3^{+15}_{-5})^\circ$, respectively, corresponding to $\dfrac{\mathcal{B}(D^0 \to K^*(892)^+\pi^-)}{\mathcal{B}(D^0 \to K^*(892)^-\pi^+)} = (0.5 \pm 0.2^{+0.5\,+0.4}_{-0.1\,-0.1})\%$.

CP Violation — In the limit of CP conservation, charge conjugate decays will have the same Dalitz-plot distribution. The $D^{*\pm}$ tag enables the discrimination between D^0 and $\overline{D}^0$. The integrated CP violation across the Dalitz plot is determined from

$$\mathcal{A}_{CP} = \int \frac{|\mathcal{M}|^2 - |\overline{\mathcal{M}}|^2}{|\mathcal{M}|^2 + |\overline{\mathcal{M}}|^2}\, dm^2_{ab}\, dm^2_{bc} \Big/ \int dm^2_{ab}\, dm^2_{bc}\,,$$

where $\mathcal{M}$ and $\overline{\mathcal{M}}$ are the D^0 and $\overline{D}^0$ Dalitz-plot amplitudes. This expression is less sensitive to CP violation than the individual resonant submodes reported in Ref. [7]. Table 5 reports the results for CP violation. No evidence of CP violation has been observed.

Table 5: Dalitz-plot-integrated CP violation.

Experiment	Decay mode	$\mathcal{A}_{CP}(\%)$
CLEO [6]	$D^0 \to K^-\pi^+\pi^0$	-3.1 ± 8.6
CLEO [5]	$D^0 \to K^+\pi^-\pi^0$	$+9^{+22}_{-25}$
CLEO [7]	$D^0 \to K^0_S\pi^+\pi^-$	$-3.9 \pm 3.4^{+1.4}_{-2.2} \pm 2.7$
CLEO [8]	$D^0 \to \pi^+\pi^-\pi^0$	$+1^{+9}_{-7} \pm 9$

The possibility of interference between CP–conserving and CP–violating amplitudes provides a more sensitive probe of CP violation. The constraints on the square of the CP–violating amplitude obtained in the resonant submodes of $D^0 \to K^0_S\pi^+\pi^-$ range form 4.5–to–29 $\times 10^{-4}$ at 95% confidence level [7].

$\Gamma(K_0^*(800)^0\pi^+)/\Gamma(K^-\pi^+\pi^+)$ Γ_{81}/Γ_{39}

The $K_0^*(800)$ is a broad scalar resonance that may not exist and is not included in the Summary Tables. AITALA 02 finds that including such a resonance in the fit to the $D^+ \to K^-\pi^+\pi^+$ Dalitz plot greatly improves the fit. However, the results of AITALA 02 for the $D^+ \to K^-\pi^+\pi^+$ Dalitz plot analysis so disagree with earlier analyses that averaging the results makes no sense. For now, we exclude AITALA 02 from the average.

Hadronic modes with a $K\overline{K}$ pair

$\Gamma(K^+\overline{K}^0)/\Gamma(\overline{K}^0\pi^+)$ Γ_{129}/Γ_{38}

It is generally assumed for modes such as $D^+\to\overline{K}^0\pi^+$ that $\Gamma(D^+\to\overline{K}^0\pi^+)=2\Gamma(D^+\to K^0_S\pi^+)$; it is the latter Γ that is actually measured. BIGI 95 points out that interference between Cabibbo-allowed and doubly Cabibbo-suppressed amplitudes, where both occur, could invalidate this assumption by a few percent.

$D^{\pm}$ PRODUCTION CROSS SECTION AT $\psi(3770)$

A compilation of the cross sections for the direct production of $D^{\pm}$ mesons at or near the $\psi(3770)$ peak in e^+e^- production.

VALUE (nanobarns)	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
$4.2 \pm 0.6 \pm 0.3$	[89] ADLER	88C	MRK3	e^+e^- 3.768 GeV
5.5 ± 1.0	[90] PARTRIDGE	84	CBAL	e^+e^- 3.771 GeV
$6.00 \pm 0.72 \pm 1.02$	[91] SCHINDLER	80	MRK2	e^+e^- 3.771 GeV
9.1 ± 2.0	[92] PERUZZI	77	MRK1	e^+e^- 3.774 GeV

[89] This measurement compares events with one detected D to those with two detected D mesons, to determine the the absolute cross section. ADLER 88C measure the ratio of cross sections (neutral to charged) to be $1.36 \pm 0.23 \pm 0.14$. This measurement does not include the decays of the $\psi(3770)$ not associated with charmed particle production.

[90] This measurement comes from a scan of the $\psi(3770)$ resonance and a fit to the cross section. PARTRIDGE 84 measures 6.4 ± 1.15 nb for the cross section. We take the phase space division of neutral and charged D mesons in $\psi(3770)$ decay to be 1.33, and we assume that the $\psi(3770)$ is an isosinglet to evaluate the cross sections. The noncharm decays (e.g. radiative) of the $\psi(3770)$ are included in this measurement and may amount to a few percent correction.

[91] This measurement comes from a scan of the $\psi(3770)$ resonance and a fit to the cross section. SCHINDLER 80 assume the phase space division of neutral and charged D mesons in $\psi(3770)$ decay to be 1.33, and that the $\psi(3770)$ is an isosinglet. The noncharm decays (e.g. radiative) of the $\psi(3770)$ are included in this measurement and may amount to a few percent correction.

[92] This measurement comes from a scan of the $\psi(3770)$ resonance and a fit to the cross section. The phase space division of neutral and charged D mesons in $\psi(3770)$ decay is taken to be 1.33, and $\psi(3770)$ is assumed to be an isosinglet. The noncharm decays (e.g. radiative) of the $\psi(3770)$ are included in this measurement and may amount to a few percent correction. We exclude this measurement from the average because of uncertainties in the contamination from τ lepton pairs. Also see RAPIDIS 77.

$D^+ \to \overline{K}^*(892)^0 \ell^+ \nu_\ell$ FORM FACTORS

$r_V \equiv V(0)/A_1(0)$ in $D^+ \to \overline{K}^*(892)^0 \ell^+ \nu_\ell$

VALUE	EVTS	DOCUMENT ID		TECN	COMMENT
1.62 ± 0.08 OUR AVERAGE		Error includes scale factor of 1.5. See the ideogram below.

D^0–$\overline{D}^0$ MIXING

Revised November 2003 by D. Asner (University of Pittsburgh)

Standard Model contributions to D^0–$\overline{D}^0$ mixing are strongly suppressed by CKM and GIM factors. Thus the observation of D^0–$\overline{D}^0$ mixing might be evidence for physics beyond the Standard Model. See Burdman and Shipsey [1] for a review of D^0–$\overline{D}^0$ mixing, Nelson [2] for a compilation of mixing predictions, and Ref. [3] for subsequent predictions.

Formalism: The time evolution of the D^0–$\overline{D}^0$ system is described by the Schrödinger equation

$$i\frac{\partial}{\partial t}\begin{pmatrix} D^0(t) \\ \overline{D}^0(t) \end{pmatrix} = \left(\mathbf{M} - \tfrac{i}{2}\mathbf{\Gamma}\right)\begin{pmatrix} D^0(t) \\ \overline{D}^0(t) \end{pmatrix}, \quad (1)$$

where the $\mathbf{M}$ and $\mathbf{\Gamma}$ matrices are Hermitian, and CPT invariance requires $M_{11} = M_{22} \equiv M$ and $\Gamma_{11} = \Gamma_{22} \equiv \Gamma$. The off-diagonal elements of these matrices describe the dispersive and absorptive parts of D^0–$\overline{D}^0$ mixing.

The two eigenstates D_1 and D_2 of the effective Hamiltonian matrix $(\mathbf{M} - \frac{i}{2}\mathbf{\Gamma})$ are given by

$$|D_{1,2}\rangle = p|D^0\rangle \pm q|\overline{D}^0\rangle\,. \quad (2)$$

The corresponding eigenvalues are

$$\lambda_{1,2} \equiv m_{1,2} - \tfrac{i}{2}\Gamma_{1,2} = \left(M - \tfrac{i}{2}\Gamma\right) \pm \frac{q}{p}\left(M_{12} - \tfrac{i}{2}\Gamma_{12}\right), \quad (3)$$

where m_1 and Γ_1 are the mass and width of the D_1, etc., and

$$\left|\frac{q}{p}\right|^2 = \frac{M_{12}^* - \frac{i}{2}\Gamma_{12}^*}{M_{12} - \frac{i}{2}\Gamma_{12}}\,. \quad (4)$$

We extend the formalism of this Review's note on "B^0–$\overline{B}^0$ Mixing" [4]. In addition to the "right-sign" instantaneous decay amplitudes $\overline{A}_f \equiv \langle f|H|\overline{D}^0\rangle$ and $A_{\overline{f}} \equiv \langle \overline{f}|H|D^0\rangle$ for CP conjugate final states f and $\overline{f}$, we include the "wrong-sign" amplitudes $\overline{A}_{\overline{f}} \equiv \langle \overline{f}|H|\overline{D}^0\rangle$ and $A_f \equiv \langle f|H|D^0\rangle$.

It is usual to normalize the wrong-sign decay distributions to the integrated rate of right-sign decays and to express time in units of the precisely measured D^0 mean lifetime, $\overline{\tau}_{D^0} = 1/\Gamma = 2/(\Gamma_1 + \Gamma_2)$. Starting from a pure $|D^0\rangle$ or $|\overline{D}^0\rangle$ state at $t = 0$, the time-dependent rates of production of the wrong-sign final states relative to the integrated right-sign states are then

$$r(t) = \frac{\left|\langle f|H|D^0(t)\rangle\right|^2}{\left|\overline{A}_f\right|^2} = \left|\frac{q}{p}\right|^2 \left|g_+(t)\,\chi_f^{-1} + g_-(t)\right|^2 \quad (5)$$

and

$$\overline{r}(t) = \frac{\left|\langle \overline{f}|H|\overline{D}^0(t)\rangle\right|^2}{\left|A_{\overline{f}}\right|^2} = \left|\frac{p}{q}\right|^2 \left|g_+(t)\,\chi_{\overline{f}} + g_-(t)\right|^2, \quad (6)$$

where

$$\chi_f = \frac{q\overline{A}_f}{pA_f} \quad (7)$$

and

$$g_\pm(t) = \frac{1}{2}\left(e^{-iz_1 t} \pm e^{-iz_2 t}\right), \quad z_{1,2} = \frac{\lambda_{1,2}}{\Gamma}\,. \quad (8)$$

Note that a change in the convention for the relative phase of D^0 and $\overline{D}^0$ would cancel between q/p and $\overline{A}_f/A_f$ and leave χ_f invariant.

Since D^0–$\overline{D}^0$ mixing is a small effect, the identification tag of the initial particle as a D^0 or a $\overline{D}^0$ must be extremely accurate. The usual tag is the charge of the distinctive slow

pion in the decay sequence $D^{*+} \to D^0\pi^+$ or $D^{*-} \to \overline{D}^0\pi^-$. In current experiments, the mis-tag probability is about one per thousand. Another tag of comparable accuracy is identification of one of the D's from $\psi(3770) \to D^0\overline{D}^0$.

We expand $r(t)$ and $\overline{r}(t)$ to second order in time for modes where the ratio of decay amplitudes $R_D = |A_f/\overline{A}_f|^2$ is very small. We define reduced mixing amplitudes x and y by

$$x \equiv \frac{2M_{12}}{\Gamma} = \frac{m_1 - m_2}{\Gamma} = \frac{\Delta m}{\Gamma} \tag{9}$$

and

$$y \equiv \frac{\Gamma_{12}}{\Gamma} = \frac{\Gamma_1 - \Gamma_2}{2\Gamma} = \frac{\Delta\Gamma}{2\Gamma}. \tag{10}$$

In these equations, the middle relation holds in the limit of CP conservation, in which case the subscripts 1 and 2 indicate the CP-even and CP-odd eigenstates, respectively.

Semileptonic decays: In semileptonic decays, $A_f = \overline{A}_{\overline{f}} = 0$ in the Standard Model. Then in the limit of weak mixing, where $|ix + y| \ll 1$, $r(t)$ is given by

$$r(t) = |g_-(t)|^2 \left|\frac{q}{p}\right|^2 \approx \frac{e^{-t}}{4}(x^2 + y^2)\, t^2 \left|\frac{q}{p}\right|^2 . \tag{11}$$

For $\overline{r}(t)$ one replaces q/p here by p/q; and in the limit of CP conservation, $r(t) = \overline{r}(t)$, and the time-integrated mixing rate relative to the time-integrated right-sign decay rate is

$$R_M = \int_0^\infty r(t)dt \approx \frac{1}{2}(x^2 + y^2)\,. \tag{12}$$

The results from semileptonic decays are summarized in Table 1. The most sensitive mixing limit is from the FOCUS experiment [5]. Searching for the decay $D^0 \to K^+\mu^-\overline{\nu}_\mu$, it found $R_M < 1.31 \times 10^{-3}$ at the 95% C.L., assuming CP conservation. Semileptonic decays are less sensitive to mixing than are hadronic decays and thus have received less attention recently.

Table 1: Results for R_M in D^0 semileptonic decays.

Year	Exper.	Final State(s)	R_M
2002	FOCUS [5]	$K^+\mu^-\overline{\nu}_\mu$	$< 1.31 \times 10^{-3}$ (95% C.L.)
2002	CLEO [6]	$K^{*+}e^-\overline{\nu}_e$	$< 8.6 \times 10^{-3}$ (95% C.L.)
1996	E791 [7]	$K^+\ell^-\overline{\nu}_\ell$	$< 5.0 \times 10^{-3}$ (90% C.L.)

Wrong-sign decays to hadronic non-CP eigenstates: Consider the final state $f = K^+\pi^-$, where A_f is doubly Cabibbo-suppressed, and the ratio of decay amplitudes is

$$\frac{A_f}{\overline{A}_f} = -\sqrt{R_D}\, e^{-i\delta}, \qquad \left|\frac{A_f}{\overline{A}_f}\right| \sim O(\tan^2\theta_c)\,, \tag{13}$$

where R_D is the doubly Cabibbo-suppressed decay rate relative to the Cabibbo-favored rate, and δ is a strong phase difference between doubly Cabibbo-suppressed and Cabibbo-favored processes. The minus sign originates from the sign of V_{us} relative to V_{cd}.

We characterize the violation of CP in the mixing amplitude, the decay amplitude, and the interference between mixing and decay, by real-valued parameters A_M, A_D, and ϕ. We adopt a parameterization similar to that of Nir [8] and CLEO [9] and express these quantities in a way that is convenient to describe the three types of CP violation:

$$\left|\frac{q}{p}\right| = 1 + A_M\,, \tag{14}$$

$$\chi_f^{-1} \equiv \frac{pA_f}{q\overline{A}_f} = \frac{-\sqrt{R_D}(1 + A_D)}{(1 + A_M)}\, e^{-i(\delta+\phi)}\,, \tag{15}$$

$$\chi_{\overline{f}} \equiv \frac{q\overline{A}_{\overline{f}}}{pA_{\overline{f}}} = -\frac{-\sqrt{R_D}(1 + A_M)}{(1 + A_D)}\, e^{-i(\delta-\phi)}\,. \tag{16}$$

In general, $\chi_{\overline{f}}$ and χ_f^{-1} are independent complex numbers. To leading order,

$$r(t) = e^{-t} \times \Big[R_D(1 + A_D)^2 + \sqrt{R_D}(1 + A_M)(1 + A_D)y'_-\, t + \frac{(1 + A_M)^2 R_M}{2}\, t^2\Big] \tag{17}$$

and

$$\overline{r}(t) = e^{-t} \times \left[\frac{R_D}{(1+A_D)^2} + \frac{\sqrt{R_D}}{(1+A_D)(1+A_M)} y'_+ t + \frac{R_M}{2(1+A_M)^2}\, t^2\right], \tag{18}$$

where

$$y'_\pm \equiv y'\cos\phi \pm x'\sin\phi = y\cos(\delta \mp \phi) - x\sin(\delta \mp \phi) \tag{19}$$

$$y' \equiv y\cos\delta - x\sin\delta, \quad x' \equiv x\cos\delta + y\sin\delta\,, \tag{20}$$

and R_M is the mixing rate relative to the time-integrated right-sign rate.

The differences between the three terms in Eq. (17) and Eq. (18) probe the three fundamental types of CP violation. In the limit of CP conservation, A_M, A_D, and ϕ are all zero, and then $r(t) = \overline{r}(t)$:

$$r(t) = \overline{r}(t) = e^{-t}\left(R_D + \sqrt{R_D}\, y' t + \frac{1}{2} R_M\, t^2\right), \tag{21}$$

and the time-integrated wrong-sign rate relative to the integrated right-sign rate is

$$R = \int_0^\infty r(t)\, dt = R_D + \sqrt{R_D}\, y' + R_M\,. \tag{22}$$

The ratio R of time-integrated wrong- and right-sign rates is the most readily accessible experimental quantity. The observations of non-zero R in $D^0 \to K^+\pi^-$ decay are summarized in Table 2. There has been improvement in precision since 1999, and the average, $R = (0.365 \pm 0.021)\,\%$, from recent experiments is about two standard deviations from the average of $R = (0.81 \pm 0.23)\,\%$ of the pre-1999 results. We restrict the subsequent discussion to the post-1999 experiments.

Table 2: Results for R in $D^0 \to K^+\pi^-$.

Year	Exper.	Technique	$R_D(\times 10^{-3})$	$A_D(\%)$
2003	BABAR [10]	$e^+e^- \to \Upsilon(4S)$	$3.57 \pm 0.22 \pm 0.27$	$9.5 \pm 6.1 \pm 8.3$
2002	Belle [11]	$e^+e^- \to \Upsilon(4S)$	$3.72 \pm 0.25^{+0.09}_{-0.14}$	-
2001	FOCUS [12]	γ BeO	$4.04 \pm 0.85 \pm 0.25$	-
2000	CLEO [9]	$e^+e^- \to \Upsilon(4S)$	$3.32^{+0.63}_{-0.65} \pm 0.40$	$2^{+19}_{-20} \pm 1$
1998	E791 [13]	π^-Pt	$6.8^{+3.4}_{-3.3} \pm 0.7$	-
1998	Aleph [14]	$e^+e^- \to Z^0$	$18.4 \pm 5.9 \pm 3.4$	-
1994	CLEO [15]	$e^+e^- \to \Upsilon(4S)$	$7.7 \pm 2.5 \pm 2.5$	-

The contributions to R can be extracted by fitting the $D^0 \to K^+\pi^-$ decay rates. Comparison of results is complicated because some experiments include CP violating terms, some do not. CLEO [9] and BABAR [10] allowed for CP violation in all three terms (i.e. measure $r(t)$ and $\overline{r}(t)$), and then quote limits on the mixing amplitudes after averaging D^0 and $\overline{D}^0$. A preliminary FOCUS result [12] assumes CP conservation. The results for y' and $x'^2/2$ are summarized in Table 3. Figure 1 shows the two-dimensional allowed regions.

Table 3: Results from studies of the time dependence $r(t)$.

Year	Exper.	y' (95% C.L.)	$x'^2/2$ (95% C.L.)
2003	BABAR [10]	$-5.6 < y' < 3.9$ %	< 0.11 %
2001	FOCUS [12]	$-12.4 < y' < -0.5$ %	< 0.076 %
2000	CLEO [9]	$-5.8 < y' < 1.0$ %	< 0.041 %

Extraction of the amplitudes x and y from the results in Table 3 requires knowledge of the relative strong phase δ, a subject of theoretical discussion [16, 17]. In most cases, it appears difficult for theory to accommodate $\delta > 25°$, although the judicious placement of a $K\pi$ resonance could allow δ to be as large as 50°.

A quantum interference effect that provides useful sensitivity to δ arises in the decay chain $\psi(3770) \to D^0\overline{D}^0 \to (f_{cp})(K^+\pi^-)$, where f_{cp} denotes a CP eigenstate from D^0 decay, such as K^+K^-[1, 18]. Here, the amplitude triangle relation

$$\sqrt{2}\,A(D_\pm \to K^-\pi^+) = A(D^0 \to K^-\pi^+) \pm A(\overline{D}^0 \to K^-\pi^+), \tag{23}$$

where $D_\pm$ denotes a CP eigenstate, implies that

$$1 \pm 2\sqrt{R_D}\cos\delta = 2\,\frac{B(D_\pm \to K^-\pi^+)}{B(D^0 \to K^-\pi^+)}, \tag{24}$$

or

$$\cos\delta = \frac{B(D_+ \to K^-\pi^+) - B(D_- \to K^-\pi^+)}{2\sqrt{R_D}\,B(D^0 \to K^-\pi^+)}, \tag{25}$$

neglecting CP violation and exploiting $R_D \ll \sqrt{R_D}$. Projections for 3 fb^{-1} of data at the $\psi(3770)$ indicate that δ could be measured to 20° if $|\cos\delta| \sim 1$, and to a few degrees if $\cos\delta \sim 0$ [19].

The strong phase δ might also be determined by constructing amplitude quadrangles from a complete set of branching fraction measurements of the other doubly Cabibbo-suppressed D decays to two pseudoscalars [20]. This analysis would have to assume that the amplitudes from both $\Delta I = 1$ and $\Delta I = 0$ that populate the total $I = 1/2$ $K\pi$ state have the same strong phase relative to the amplitude that populates the total $I = 3/2$ $K\pi$ state.

The Dalitz-plot analyses of doubly Cabibbo-suppressed D decays to a pseudoscalar and a vector allow the measurement of the relative strong phase between some amplitudes, providing additional contraints to the amplitude quadrangle [21] and thus the determination of the strong phase difference between the relevant doubly Cabibbo-suppressed and Cabibbo-favored amplitudes. In $D^0 \to K_S\pi\pi$, the doubly Cabibbo-suppressed and Cabibbo-favored decay amplitudes occupy the same Dalitz plot, which allows direct measurement of the relative strong phase. CLEO has measured the relative phase between $D^0 \to K^*(892)^+\pi^-$ and $D^0 \to K^*(892)^-\pi^+$ to be $(189 \pm 10 \pm 3^{+15}_{-5})°$ [22], consistent with the 180° expected from Cabibbo factors and a small strong phase.

There are several results for R measured in multibody final states with nonzero strangeness. Here R, defined in Eq. (22), becomes an average over the Dalitz space, weighted by experimental efficiencies and acceptance. The results are summarized in Table 4.

Table 4: Results for R in $D^0 \to K^{(*)+}\pi^-(n\pi)$.

Year	Exper.	D^0 Final State	$R(\%)$
2002	CLEO [22]	$K^*(892)^+\pi^-$	$0.5 \pm 0.2^{+0.6}_{-0.1}$
2001	CLEO [23]	$K^+\pi^-\pi^+\pi^-$	$0.41^{+0.12}_{-0.11} \pm 0.04$
2001	CLEO [24]	$K^+\pi^-\pi^0$	$0.43^{+0.11}_{-0.10} \pm 0.07$
1998	E791 [13]	$K^+\pi^-\pi^+\pi^-$	$0.68^{+0.34}_{-0.33} \pm 0.07$

For multibody final states, Eqs. (13)–(22) apply to one point in the Dalitz space. Although x and y do not vary across the Dalitz space, knowledge of the resonant substructure is needed to extrapolate the strong phase difference δ from point to point. Both the sign and magnitude of x and y are experimentally accessible by studying the time-dependent resonant substructure in decay modes such as $D^0 \to K_S\pi^+\pi^-$ [25].

Decays to CP Eigenstates: When the final state f is a CP eigenstate, there is no distinction between f and $\overline{f}$, and then $A_f = A_{\overline{f}}$ and $\overline{A}_{\overline{f}} = \overline{A}_f$. We denote final states with CP eigenvalues ± 1 by $f_\pm$. In analogy with Eqs. (5)–(6), the decay rates to CP eigenstates are then

$$\begin{aligned} r_\pm(t) &= \frac{\left|\langle f_\pm|H|D^0(t)\rangle\right|^2}{\left|\overline{A}_\pm\right|^2} \\ &= \frac{1}{4}\left|h_\pm(t)\left(\frac{A_\pm}{\overline{A}_\pm} \pm \frac{q}{p}\right) + h_\mp(t)\left(\frac{A_\pm}{\overline{A}_\pm} \mp \frac{q}{p}\right)\right|^2, \\ &\propto \frac{1}{|p|^2}\left|h_\pm(t) + \eta_\pm h_\mp(t)\right|^2, \end{aligned} \tag{26}$$

and

$$\overline{r}_\pm(t) = \frac{\left|\langle f_\pm|H|\overline{D}^0(t)\rangle\right|^2}{|A_\pm|^2} \propto \frac{1}{|q|^2}\left|h_\pm(t) - \eta_\pm h_\mp(t)\right|^2, \quad (27)$$

where

$$h_\pm(t) = g_+(t) \pm g_-(t) = e^{-iz_\pm t}, \quad (28)$$

and

$$\eta_\pm \equiv \frac{pA_\pm \mp q\overline{A}_\pm}{pA_\pm \pm q\overline{A}_\pm} = \frac{1 \mp \chi_\pm}{1 \pm \chi_\pm}, \quad (29)$$

and the variable $\eta_\pm$ describes CP violation; $\eta_\pm$ can receive contributions from each of the three fundamental types of CP violation.

The quantity y may be measured by comparing the rate for decays to non-CP eigenstates such as $D^0 \to K^-\pi^+$ with decays to CP eigenstates such as $D^0 \to K^+K^-$ [17]. A positive y would make K^+K^- decays appear to have a higher decay rate than $K^-\pi^+$ decays. The decay rate for a D^0 into a CP eigenstate is not described by a single exponential in the presence of CP violation.

In the limit of weak mixing, where $|ix+y| \ll 1$, and small CP violation, where $|A_M|$, $|A_D|$, and $|\sin\phi| \ll 1$, the time dependence of decays to CP eigenstates is proportional to a single exponential:

$$r_\pm(t) \propto e^{-[1\pm\left|\frac{p}{q}\right|(y\cos\phi - x\sin\phi)]t}, \quad (30)$$

$$\overline{r}_\pm(t) \propto e^{-[1\pm\left|\frac{q}{p}\right|(y\cos\phi + x\sin\phi)]t}, \quad (31)$$

$$r_\pm(t) + \overline{r}_\pm(t) \propto e^{-(1\pm y_{CP})t}. \quad (32)$$

Here

$$y_{CP} = y\cos\phi\left[\frac{1}{2}\left(\left|\frac{p}{q}\right| + \left|\frac{q}{p}\right|\right) + \frac{A_{\rm prod}}{2}\left(\left|\frac{p}{q}\right| - \left|\frac{q}{p}\right|\right)\right] - x\sin\phi\left[\frac{1}{2}\left(\left|\frac{p}{q}\right| - \left|\frac{q}{p}\right|\right) + \frac{A_{\rm prod}}{2}\left(\left|\frac{p}{q}\right| + \left|\frac{q}{p}\right|\right)\right], \quad (33)$$

and

$$A_{\rm prod} \equiv \frac{N(D^0) - N(\overline{D}^0)}{N(D^0) + N(\overline{D}^0)} \quad (34)$$

is defined as the production asymmetry of the D^0 and $\overline{D}^0$. Note that deviations from the decay rate measured in non-CP eigenstates does not require $y \neq 0$ but can be due to $x\sin\phi \neq 0$. This possibility is distinguished by a relative sign difference in the exponents of Eqs. (30) and (31) describing the D^0 and $\overline{D}^0$ samples, respectively.

In the limit of CP conservation, $A_\pm = \pm\overline{A}_\pm$, $\eta_\pm = 0$, $y = y_{CP}$, and

$$r_\pm(t)\left|\overline{A}_\pm\right|^2 = \overline{r}_\pm(t)\left|A_\pm\right|^2 = e^{-(1\pm y_{CP})t}. \quad (35)$$

The possibility of CP violation has not been considered in general in any of the analyses of y, although specific cases have been considered. Belle [26] and BABAR [27] have allowed CP violation in interference and mixing. Neither result considered CP violation in direct decay. All measurements are relative to the $D^0 \to K^-\pi^+$ decay rate. The current status of measurements of y is summarized in Table 5 and in Fig. 1.

Table 5: Results for y from $D^0 \to K^+K^-$ and $\pi^+\pi^-$.

Year	Exper.	D^0 Final State(s)	$y(\%)$
2003	Belle [26]	K^+K^-	$y_{CP} = 1.15 \pm 0.69 \pm 0.38$
2003	BABAR [27]	$K^+K^-, \pi^+\pi^-$	$y\cos\phi = 0.8 \pm 0.4^{+0.5}_{-0.4}$
2001	CLEO [28]	$K^+K^-, \pi^+\pi^-$	$y_{CP} = -1.1 \pm 2.5 \pm 1.4$
2001	Belle [29]	K^+K^-	$y_{CP} = -0.5 \pm 1.0^{+0.7}_{-0.8}$
2000	FOCUS [30]	K^+K^-	$y_{CP} = 3.4 \pm 1.4 \pm 0.7$
1999	E791 [31]	K^+K^-	$y_{CP} = 0.8 \pm 2.9 \pm 1.0$

Substantial work on the integrated CP asymmetries in decays to CP eigenstates indicates that A_{CP} is consistent with zero at the few percent level [32]. The expression for the integrated CP asymmetry that includes the possibility of CP violation in mixing is

$$A_{CP} = \frac{\Gamma(D^0 \to f_\pm) - \Gamma(\overline{D}^0 \to f_\pm)}{\Gamma(D^0 \to f_\pm) + \Gamma(\overline{D}^0 \to f_\pm)} \quad (36)$$

$$= \frac{|q|^2 - |p|^2}{|q|^2 + |p|^2} + 2\mathrm{Re}(\eta_\pm). \quad (37)$$

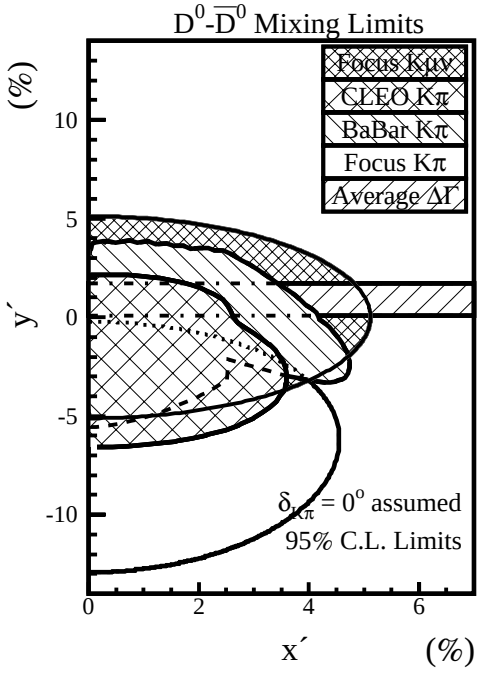

Figure 1: Current allowed regions in the plane of y' versus x'. The regions for CLEO and BaBar allow CP violation in the decay amplitude, in the mixing amplitude, and in the interference between these two processes. The FOCUS result does not allow CP violation. The allowed region for $\Delta\Gamma$ is the average of the y_{CP} [26, 28–31] results and the BABAR measurement of $y\cos\phi$ [27] and does not include $y = 0$. We assume $\delta = 0$ to place the $\Delta\Gamma$ results. A non-zero value for δ would rotate this confidence region clockwise about the origin by an angle δ. [5] This GODANG 00 limit is inferred from the D^0-$\overline{D}^0$ mixing ratio $\Gamma(K^+\pi^-$ (via $\overline{D}^0$))/$\Gamma(K^-\pi^+)$ given near the end of this D^0 Listings. Decay-time information is used to distinguish DCS decays from D^0-$\overline{D}^0$ mixing. The limit allows interference between the DCS and mixing ratios, and also allows CP violation. The strong phase between $D^0 \to K^+\pi^-$ and $\overline{D}^0 \to K^+\pi^-$ is assumed to be small. If an arbitrary relative strong phase is allowed, the limit degrades by a factor of two.

[6] This AUBERT 03Z limit is inferred from the D^0-$\overline{D}^0$ mixing ratio $\Gamma(K^+\pi^-$ (via $\overline{D}^0$))/$\Gamma(K^-\pi^+)$ given near the end of this D^0 Listings. Decay-time information is used to distinguish DCS decays from D^0-$\overline{D}^0$ mixing. The limit allows interference between the DCS and mixing ratios, and also allows CP violation. The strong phase between $D^0 \to K^+\pi^-$ and $\overline{D}^0 \to K^+\pi^-$ is assumed to be small. If an arbitrary relative strong phase is allowed, the limit degrades by 20%.

[7] AITALA 98 allows interference between the doubly Cabibbo-suppressed and mixing amplitudes, and also allows CP violation in this term, but assumes that A_D=A_R=0. See the note on "D^0-$\overline{D}^0$ Mixing," above.

[8] This limit is inferred from R_M for $f = K^+\pi^-$ and $f = K^+\pi^-\pi^+\pi^-$. See the note on "D^0-$\overline{D}^0$ Mixing," above. Decay-time information is used to distinguish doubly Cabibbo-suppressed decays from D^0-$\overline{D}^0$ mixing.

[9] This limit is inferred from R_M for $f = K^+\ell^-\overline{\nu}_\ell$. See the note on "$D^0$-$\overline{D}^0$ Mixing," above.

[10] ANJOS 88C assumes that $y = 0$. See the note on "D^0-$\overline{D}^0$ Mixing," above. Without this assumption, the limit degrades by about a factor of two.

$(\Gamma_{D_1^0} - \Gamma_{D_2^0})/\Gamma = 2y$

The D_1^0 and D_2^0 are the mass eigenstates of the D^0 meson, as described in the note on "D^0-$\overline{D}^0$ Mixing," above.

[11] AUBERT 03P measures $\Upsilon \equiv 2\tau^0/(\tau^+ + \tau^-) - 1$, where τ^0 is the $D^0 \to K^-\pi^+$ (and $\overline{D}^0 \to K^+\pi^-$) lifetime, and τ^+ and τ^- are the D^0 and $\overline{D}^0$ lifetimes to CP-even states (here K^-K^+ and $\pi^-\pi^+$). In the limit of CP conservation, $\Upsilon = y \equiv \Delta\Gamma/2\Gamma$ (we list $2y = \Delta\Gamma/\Gamma$). AUBERT 03P also uses $\tau^+ - \tau^-$ to get $\Delta Y = -0.008 \pm 0.006 \pm 0.002$.

[12] LINK 00, AITALA 99E, and ABE 02I measure the lifetime difference between $D^0 \to K^-K^+$ (CP even) decays and $D^0 \to K^-\pi^+$ (CP mixed) decays, or $y_{CP} = [\Gamma(CP+) - \Gamma(CP-)]/[\Gamma(CP+) + \Gamma(CP-)]$. We list $2y_{CP} = \Delta\Gamma/\Gamma$.

[13] CSORNA 02 measures the lifetime difference between $D^0 \to K^-K^+$ and $\pi^-\pi^+$ (CP even) decays and $D^0 \to K^-\pi^+$ (CP mixed) decays, or $y_{CP} = [\Gamma(CP+) - \Gamma(CP-)]/[\Gamma(CP+) + \Gamma(CP-)]$. We list $2y_{CP} = \Delta\Gamma/\Gamma$.

[14] The range of this AUBERT 03Z measurement is for 95% confidence level.

[15] The GODANG 00 and AUBERT 03Z limits are inferred from the D^0-$\overline{D}^0$ mixing ratio $\Gamma(K^+\pi^-$ (via $\overline{D}^0))/\Gamma(K^-\pi^+)$ given near the end of this D^0 Listings. Decay-time information is used to distinguish DCS decays from D^0-$\overline{D}^0$ mixing. The limit allows interference between the DCS and mixing ratios, and also allows CP violation. The phase between $D^0 \to K^+\pi^-$ and $\overline{D}^0 \to K^+\pi^-$ is assumed to be small. This is a measurement of y' and is not the same as the y_{CP} of our note above on "D^0-$\overline{D}^0$ Mixing."

[16] AITALA 98 allows interference between the doubly Cabibbo-suppressed and mixing amplitudes, and also allows CP violation in this term, but assumes that $A_D = A_R = 0$. See the note on "D^0-$\overline{D}^0$ Mixing," above.

[17] This limit is inferred from R_M for $f = K^+\pi^-$ and $f = K^+\pi^-\pi^+\pi^-$. See the note on "D^0-$\overline{D}^0$ Mixing," above. Decay-time information is used to distinguish doubly Cabibbo-suppressed decays from D^0-$\overline{D}^0$ mixing.

[18] This limit is inferred from R_M for $f = K^+\ell^-\overline{\nu}_\ell$. See the note on "$D^0$-$\overline{D}^0$ Mixing," above.

[19] ANJOS 88C assumes that $y = 0$. See the note on "D^0-$\overline{D}^0$ Mixing," above. Without this assumption, the limit degrades by about a factor of two.

D^0 DECAY MODES

$\overline{D}^0$ modes are charge conjugates of the modes below.

	Mode		Fraction (Γ_i/Γ)	Scale factor/ Confidence level

[*a*] The exclusive e^+ modes $K^-e^+\nu_e$, $K^-\pi^0e^+\nu_e$, $\overline{K}^0\pi^-e^+\nu_e$ and $\pi^-e^+\nu_e$ are constrained to equal this (well-measured) inclusive fraction.

[*b*] This is a weighted average of $D^\pm$ (44%) and D^0 (56%) branching fractions. See "D^+ and $D^0 \to$ (η anything) / (total D^+ and D^0)" under "D^+ Branching Ratios" in these Particle Listings.

[*c*] This value averages the e^+ and μ^+ branching fractions, after making a small phase-space adjustment to the μ^+ fraction to be able to use it as an e^+ fraction; hence our ℓ^+ here is really an e^+.

[*d*] The branching fraction for this mode may differ from the sum of the submodes that contribute to it, due to interference effects. See the relevant papers.

[*e*] The two experiments measuring this fraction are in serious disagreement. See the Particle Listings.

[*f*] The experiments on the division of this charge mode amongst its submodes disagree, and the submode branching fractions here add up to considerably more than the charged-mode fraction.

[*g*] However, these upper limits are in serious disagreement with values obtained in another experiment.

[*h*] This mode is not a useful test for a ΔC=1 weak neutral current because both quarks must change flavor in this decay.

[*i*] The value is for the sum of the charge states or particle/antiparticle states indicated.

CONSTRAINED FIT INFORMATION

An overall fit to 58 branching ratios uses 125 measurements and one constraint to determine 32 parameters. The overall fit has a $\chi^2 = 67.2$ for 94 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\rm total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

0.0391±0.0008±0.0017	4208	[40,46] AKERIB	93	CLE2	See ARTUSO 98

[39] This combines the CLEO results of ARTUSO 98, COAN 98, and AKERIB 93.

[40] ABACHI 88, DECAMP 91J, AKERIB 93, ALBRECHT 94F, and BARATE 97C use $D^*(2010)^+ \to D^0\pi^+$ decays. The π^+ is both slow and of low p_T with respect to the event thrust axis or nearest jet (≈ D^{*+} direction). The excess number of such π^+'s over background gives the number of $D^*(2010)^+ \to D^0\pi^+$ events, and the fraction with $D^0 \to K^-\pi^+$ gives the $D^0 \to K^-\pi^+$ branching fraction.

[41] ALBRECHT 94 uses D^0 mesons from $\overline{B}^0 \to D^{*+}\ell^-\overline{\nu}_\ell$ decays. This is a different set of events than used by ALBRECHT 94F.

[42] SCHINDLER 81 (MARK-2) measures $\sigma(e^+e^- \to \psi(3770)) \times$ branching fraction to be 0.24 ± 0.02 nb. We use the MARK-3 (ADLER 88C) value of σ = 5.8 ± 0.5 ± 0.6 nb.

[43] PERUZZI 77 (MARK-1) measures $\sigma(e^+e^- \to \psi(3770)) \times$ branching fraction to be 0.25 ± 0.05 nb. We use the MARK-3 (ADLER 88C) value of σ = 5.8 ± 0.5 ± 0.6 nb.

[44] ARTUSO 98, following ALBRECHT 94, uses D^0 mesons from $\overline{B}^0 \to D^*(2010)^+X\ell^-\overline{\nu}_\ell$ decays. Our average uses the CLEO average of this value with the values of COAN 98 and AKERIB 93.

[45] COAN 98 assumes that $\Gamma(B \to \overline{D}X\ell^+\nu)/\Gamma(B \to X\ell^+\nu) = 1.0 - 3|V_{ub}/V_{cb}|^2 - 0.010 \pm 0.005$, the last term accounting for $\overline{B} \to D_s^+KX\ell^-\overline{\nu}$. COAN 98 is included in the CLEO average in ARTUSO 98.

[46] This AKERIB 93 value does not include radiative corrections; with them, the value is 0.0395 ± 0.0008 ± 0.0017. AKERIB 93 is included in the CLEO average in ARTUSO 98.

0.062 ± 0.019	44	[56] PERUZZI	77	MRK1	e^+e^- 3.77 GeV

[53] ALBRECHT 94 uses D^0 mesons from $\overline{B}^0 \to D^{*+}\ell^-\overline{\nu}_\ell$ decays. This is a different set of events than used by ALBRECHT 94F.

[54] See the footnote on the ALBRECHT 94F measurement of $\Gamma(K^-\pi^+)/\Gamma_{\text{total}}$ for the method used.

[55] SCHINDLER 81 (MARK-2) measures $\sigma(e^+e^- \to \psi(3770)) \times$ branching fraction to be 0.68 ± 0.11 nb. We use the MARK-3 (ADLER 88C) value of $\sigma = 5.8 \pm 0.5 \pm 0.6$ nb.

[56] PERUZZI 77 (MARK-1) measures $\sigma(e^+e^- \to \psi(3770)) \times$ branching fraction to be 0.36 ± 0.10 nb. We use the MARK-3 (ADLER 88C) value of $\sigma = 5.8 \pm 0.5 \pm 0.6$ nb.

$0.209^{+0.074}_{-0.043} \pm 0.012$	9	[63] AGUILAR-...	87F	HYBR	πp, pp 360, 400 GeV

[63] AGUILAR-BENITEZ 87F and BARLAG 92C compute the branching fraction using topological normalization. They do not distinguish the presence of a third π^0, and thus are not included in the average.

[64] ADLER 88C uses an absolute normalization method finding this decay channel opposite a detected $\overline{D}^0 \to K^+\pi^-$ in pure $D\overline{D}$ events.

Rare or forbidden modes

$\Gamma(K^+\ell^-\overline{\nu}_\ell(\text{via }\overline{D}^0))/\Gamma(K^-\ell^+\nu_\ell)$ Γ_{173}/Γ_8

This is a limit on R_M without the complications of possible doubly-Cabibbo-suppressed decays that occur when using hadronic modes. For the limits on $|m_1 - m_2|$ and $(\Gamma_1 - \Gamma_2)/\Gamma$ that come from the best mixing limit, see near the beginning of these D^0 Listings.

VALUE	CL%	DOCUMENT ID		TECN	COMMENT
< 0.005	90	[91] AITALA	96C	E791	π^- nucleus, 500 GeV

[91] AITALA 96C uses $D^{*+} \to D^0\pi^+$ (and charge conjugate) decays to identify the charm at production and $D^0 \to K^-\ell^+\nu_\ell$ (and charge conjugate) decays to identify the charm at decay.

$\Gamma(K^+\pi^-)/\Gamma(K^-\pi^+)$ Γ_{174}/Γ_{20}

This is R_D in the note on "D^0-$\overline{D}^0$ Mixing." near the start of the D^0 Listings. The experiments here use the charge of the pion in $D^*(2010)^\pm \to (D^0 \text{ or } \overline{D}^0)\,\pi^\pm$ decay to tell whether a D^0 or a $\overline{D}^0$ was born. The $D^0 \to K^+\pi^-$ decay can occur directly by doubly Cabibbo-suppressed (DCS) decay, or indirectly by $D^0 \to \overline{D}^0$ mixing followed by $\overline{D}^0 \to K^+\pi^-$ decay. Some of the experiments can use the decay-time information to disentangle the two mechanisms. Here, we list the experimental branching ratio, which if there is no mixing is the DCS ratio. See the next data block for limits on the mixing ratio R_M, see the section on CP-violating asymmetries near the end of this D^0 Listing for values of A_D, and see the note on "D^0-$\overline{D}^0$ Mixing" for limits on x' and y'.

Some early limits have been omitted from this Listing; see our 1998 edition (EPJ **C3** 1).

< 0.014	90		[97] ALBRECHT	87K	ARG	e^+e^- 10 GeV

[92] This AUBERT 03Z result is for no mixing or CP violation. If CP violation but no mixing is allowed, R_D=0.00357 ± 0.00022 ± 0.00027. If only mixing is allowed, the 95% confidence-level interval is $(2.4 < R_D < 4.9)\times10^{-3}$. If both mixing and CP violation are allowed, this interval becomes $(2.3 < R_D < 5.2)\times10^{-3}$.

[93] This LINK 01 result assumes no mixing or CP violation; see Fig. 4 of the paper for the DCS value as a function of the (unknown) mixing parameters x' and y'. See also the note on "D^0-$\overline{D}^0$ Mixing" near the start of the D^0 Listings for results on x' and y' from FOCUS and other experiments.

[94] This GODANG 00 result assumes no D^0-$\overline{D}^0$ mixing (R_M=0 in the note on "D^0-$\overline{D}^0$ Mixing" near the start of the D^0 Listings) but allows CP violation. The DCS ratio becomes 0.0048 ± 0.0012 ± 0.0004 when mixing is allowed.

[95] This AITALA 98 result assumes no CP violation or mixing (R_M=0 in the note on "D^0-$\overline{D}^0$ Mixing" near the start of the D^0 Listings). The DCS ratio becomes $0.0090^{+0.0120}_{-0.0109} \pm 0.0044$ when mixing is allowed.

[96] BARATE 98W gets $0.0177^{+0.0060}_{-0.0056} \pm 0.0031$ for the DCS ratio when mixing is allowed, assuming no interference between the DCS and mixing amplitudes ($y' = 0$ in the note on "D^0-$\overline{D}^0$ Mixing" near the start of the D^0 Listings).

[97] CINABRO 94, AMMAR 91, and ALBRECHT 87K cannot distinguish between doubly Cabibbo-suppressed decay and D^0-$\overline{D}^0$ mixing.

[98] ANJOS 88C allows mixing but assumes no interference between the DCS and mixing amplitudes ($y' = 0$ in the note on "D^0-$\overline{D}^0$ Mixing" near the start of the D^0 Listings). When interference is allowed, the limit degrades to 0.049.

$\Gamma(K^+\pi^-(\text{via }\overline{D}^0))/\Gamma(K^-\pi^+)$ Γ_{175}/Γ_{20}

This is R_M in the note on "D^0-$\overline{D}^0$ Mixing" near the start of the D^0 Listings. The experiments here (1) use the charge of the pion in $D^*(2010)^\pm \to (D^0 \text{ or } \overline{D}^0)\,\pi^\pm$ decay to tell whether a D^0 or a $\overline{D}^0$ was born; and (2) use the decay-time distribution to disentangle doubly Cabibbo-suppressed decay and mixing. For the limits on $|m_1 - m_2|$ and $(\Gamma_1 - \Gamma_2)/\Gamma$ that come from the best mixing limit, see near the beginning of these D^0 Listings.

< 0.018	90	5 ± 12	[106] ANJOS	88C	E691	Photoproduction

[104] AMMAR 91 cannot and DYTMAN 01 does not distinguish between doubly Cabibbo-suppressed decay and D^0-$\overline{D}^0$ mixing.

[105] This AITALA 98 result assumes no D^0-$\overline{D}^0$ mixing (R_M in the note on "D^0-$\overline{D}^0$ Mixing"). It becomes $-0.0020^{+0.0117}_{-0.0106} \pm 0.0035$ when mixing is allowed and decay-time information is used to distinguish doubly Cabibbo-suppressed decays from mixing.

[106] ANJOS 88C uses decay-time information to distinguish doubly Cabibbo-suppressed (DCS) decays from D^0-$\overline{D}^0$ mixing. However, the result assumes no interference between the DCS and mixing amplitudes ($y' = 0$ in the note on "D^0-$\overline{D}^0$ Mixing" near the start of the D^0 Listings). When interference is allowed, the limit degrades to 0.033.

$\Gamma(K^+\pi^-\pi^+\pi^-$ (via $\overline{D}^0))/\Gamma(K^-\pi^+\pi^+\pi^-)$ Γ_{179}/Γ_{46}

This is a D^0-$\overline{D}^0$ mixing limit. The experiments here (1) use the charge of the pion in $D^*(2010)^\pm \to (D^0$ or $\overline{D}^0)\,\pi^\pm$ decay to tell whether a D^0 or a $\overline{D}^0$ was born; and (2) use the decay-time distribution to disentangle doubly Cabibbo-suppressed decay and mixing. For the limits on $\left|m_{D_1^0} - m_{D_2^0}\right|$ and $(\Gamma_{D_1^0} - \Gamma_{D_2^0})/\Gamma_{D^0}$ that come from the best mixing limit, see near the beginning of these D^0 Listings.

• • • We do not use the following data for averages, fits, limits, etc. • • •					
< 0.0037	90	[109] ANJOS	88C	E691	Photoproduction

[108] AITALA 98 uses decay-time information to distinguish doubly Cabibbo-suppressed decays from D^0-$\overline{D}^0$ mixing. The fit allows interference between the two amplitudes, and also allows CP violation in this term. The central value obtained is $0.0039^{+0.0036}_{-0.0032} \pm 0.0016$. When interference is disallowed, the result becomes $0.0021 \pm 0.0009 \pm 0.0002$.

[109] This combines results of ANJOS 88C on $K^+\pi^-$ and $K^+\pi^-\pi^+\pi^-$ (via $\overline{D}^0$) reported in the data block above (see footnotes there). It assumes no interference.

$\Gamma(\mu^-$ anything (via $\overline{D}^0))/\Gamma(\mu^+$ anything) Γ_{181}/Γ_2

This is a D^0-$\overline{D}^0$ mixing limit. See the somewhat better limits above.

D^0 *CPT*-VIOLATING DECAY-RATE ASYMMETRIES

$A_{CPT}(K^\mp\pi^\pm)$ in $D^0 \to K^-\pi^+, \overline{D}^0 \to K^+\pi^-$

$A_{CPT}(t)$ is defined in terms of the time-dependent decay probabilities $P(D^0 \to K^-\pi^+)$ and $\overline{P}(\overline{D}^0 \to K^+\pi^-)$ by $A_{CPT}(t) = (\overline{P}-P)/(\overline{P}+P)$. For small mixing parameters $x \equiv \Delta m/\Gamma$ and $y \equiv \Delta\Gamma/2\Gamma$ (as is the case), and times t, $A_{CPT}(t)$ reduces to $[\, y\ Re\,\xi - x\ Im\,\xi\,]\ \Gamma t$, where ξ is the *CPT*-violating parameter.

The following is actually $y\ Re\,\xi - x\ Im\,\xi$.

Meson Particle Listings

D^0, $D^*(2007)^0$

130 This measurement compares events with one detected D to those with two detected D mesons, to determine the the absolute cross section. ADLER 88C find the ratio of cross sections (neutral to charged) to be $1.36 \pm 0.23 \pm 0.14$.

131 This measurement comes from a scan of the $\psi(3770)$ resonance and a fit to the cross section. PARTRIDGE 84 measures 6.4 ± 1.15 nb for the cross section. We take the phase space division of neutral and charged D mesons in $\psi(3770)$ decay to be 1.33, and we assume that the $\psi(3770)$ is an isosinglet to evaluate the cross sections. The noncharm decays (e.g. radiative) of the $\psi(3770)$ are included in this measurement and may amount to a few percent correction.

132 This measurement comes from a scan of the $\psi(3770)$ resonance and a fit to the cross section. SCHINDLER 80 assume the phase space division of neutral and charged D mesons in $\psi(3770)$ decay to be 1.33, and that the $\psi(3770)$ is an isosinglet. The noncharm decays (e.g. radiative) of the $\psi(3770)$ are included in this measurement and may amount to a few percent correction.

133 This measurement comes from a scan of the $\psi(3770)$ resonance and a fit to the cross section. The phase space division of neutral and charged D mesons in $\psi(3770)$ decay is taken to be 1.33, and $\psi(3770)$ is assumed to be an isosinglet. The noncharm decays (e.g. radiative) of the $\psi(3770)$ are included in this measurement and may amount to a few percent correction. We exclude this measurement from the average because of uncertainties in the contamination from τ lepton pairs. Also see RAPIDIS 77.

CONSTRAINED FIT INFORMATION

An overall fit to a branching ratio uses 3 measurements and one constraint to determine 2 parameters. The overall fit has a $\chi^2 = 0.5$ for 2 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\rm total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

ABREU	98M	PL B426 231	P. Abreu *et al.*	(DELPHI Collab.)

CHARMED, STRANGE MESONS ($C = S = \pm 1$)

$D_s^+ = c\bar{s}$, $D_s^- = \bar{c}s$, similarly for D_s^*'s

$D_s^\pm$ was $F^\pm$

$I(J^P) = 0(0^-)$

The angular distributions of the decays of the ϕ and $\overline{K}^*(892)^0$ in the $\phi\pi^+$ and $K^+\overline{K}^*(892)^0$ modes strongly indicate that the spin is zero. The parity given is that expected of a $c\bar{s}$ ground state.

$D_s^\pm$ MASS

The fit includes $D^\pm$, D^0, $D_s^\pm$, $D^{*\pm}$, D^{*0}, and $D_s^{*\pm}$ mass and mass difference measurements. Measurements of the $D_s^\pm$ mass with an error greater than 10 MeV are omitted from the fit and average. A number of early measurements have been omitted altogether.

[a] For now, we average together measurements of the $Xe^+\nu_e$ and $X\mu^+\nu_\mu$ branching fractions. This is the *average*, not the *sum*.

[b] The branching fraction for this mode may differ from the sum of the submodes that contribute to it, due to interference effects. See the relevant papers.

[c] This branching fraction includes all the decay modes of the final-state resonance.

[d] This value includes only K^+K^- decays of the intermediate resonance, because branching fractions of this resonance are not known.

[e] This value includes only $\pi^+\pi^-$ decays of the intermediate resonance, because branching fractions of this resonance are not known.

[f] This mode is not a useful test for a ΔC=1 weak neutral current because both quarks must change flavor in this decay.

[g] The value is for the sum of the charge states or particle/antiparticle states indicated.

CONSTRAINED FIT INFORMATION

An overall fit to 12 branching ratios uses 24 measurements and one constraint to determine 9 parameters. The overall fit has a $\chi^2 = 13.0$ for 16 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\rm total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

Leptonic and semileptonic modes

D_s^+ DECAY CONSTANT

Written October 2003 by A. Edwards and P. Burchat (Stanford University)

In the Standard Model, the D_s^+ leptonic branching fractions are related to the D_s^+ decay constant f_{D_s} by the equation [1]

$$\mathrm{B}(D_s^+ \to \ell^+\nu_\ell) = \frac{G_F^2}{8\pi}|V_{cs}|^2 f_{D_s}^2 \frac{\tau_{D_s}}{\hbar} m_{D_s} m_\ell^2 \left(1 - \frac{m_\ell^2}{m_{D_s}^2}\right)^2 . \quad (1)$$

Hence, measurements of $\mathrm{B}(D_s^+ \to \ell^+\nu_\ell)$ can be used to extract f_{D_s}. Eight experiments have published measurements of the branching fraction for D_s^+ decaying to $\mu^+\nu_\mu$ or $\tau^+\nu_\tau$: WA75

(AOKI 93), BES (BAI 95), E653 (KODAMA 96), L3 (ACCIARRI 97F), CLEO (CHADHA 98), BEATRICE (ALEXANDROV 00), OPAL (ABBIENDI 01L), and ALEPH (HEISTER 02I). All these experiments except BES either explicitly or implicitly measure the leptonic branching fraction relative to the branching fraction for $D_s^+ \to \phi\pi^+$, or for semileptonic D_s^+ or D^0 decays. The semileptonic D_s^+ branching fraction is in turn measured relative to $B(D_s^+ \to \phi\pi^+)$. The fractional experimental uncertainty on $B(D_s^+ \to \phi\pi^+)$ is currently 25%. The LEP experiments (L3, OPAL, ALEPH) share a 23% correlated uncertainty in the normalization of the leptonic branching fraction. They use the partial decay rate for $Z \to c\bar{c}$ and the D_s^+ production rate in $Z \to c\bar{c}$ events, which in turn depends on the assumed value of $B(D_s^+ \to \phi\pi^+)$. BES uses the relative number of events in which one or two D_s decays are fully reconstructed to determine the absolute $D_s^+ \to \mu^+\nu_\mu$ branching fraction; however, only three events are observed in which one D_s^+ decays to a hadronic final state and the other decays to $\mu^+\nu_\mu$ or $\tau^+\nu_\tau$.

We determine the world average value of f_{D_s} from the experimental measurements of the D_s^+ leptonic branching fractions, assuming lepton universality, taking into account correlated uncertainties, and using a consistent and up-to-date set of input parameters [2] for the μ, τ, and D_s^+ masses, the D_s^+ lifetime, V_{cs}, $B(D_s^+ \to \phi\pi^+)$, and the relative D_s^+ branching fractions. Although the uncertainty on $B(D_s^+ \to \phi\pi^+)$ is by far the largest correlated uncertainty, we also take into account correlated uncertainties in the input parameters. Weighting each measurement by its uncorrelated uncertainty, we determine the average leptonic branching fraction for all experiments except BES to be $B(D_s^+ \to \mu^+\nu_\mu) = 0.00547 \pm 0.00067 \pm 0.00132$, where the second uncertainty in the average is the correlated uncertainty due to $B(D_s^+ \to \phi\pi^+)$. Since the above average is less (by 1.5σ) than the BES result of $B(D_s^+ \to \mu^+\nu_\mu) = 0.015^{+0.013+0.003}_{-0.006-0.002}$, the negative uncertainties on the BES measurement are used to calculate the weighted average for all experiments:

$$B(D_s^+ \to \mu^+\nu_\mu) = 0.00596 \pm 0.00144 \ . \qquad (2)$$

Using this value of the branching fraction and including the relatively minor uncertainties on the other parameters in Eq. (1), we extract the world average D_s^+ decay constant:

$$f_{D_s} = (267 \pm 33) \ \text{MeV} \ . \qquad (3)$$

• • • We do not use the following data for averages, fits, limits, etc. • • •					
$0.0068 \pm 0.0011 \pm 0.0018$	553	[5] HEISTER	02I	ALEP	Z decays
$0.015\ ^{+0.013}_{-0.006}\ ^{+0.003}_{-0.002}$	3	[6] BAI	95	BES	$e^+e^- \to D_s^+ D_s^-$
$0.004\ ^{+0.0018}_{-0.0014}\ ^{+0.0020}_{-0.0019}$	8	[7] AOKI	93	WA75	π^- emulsion 350 GeV
< 0.03	0	[8] AUBERT	83	SPEC	μ^+Fe, 250 GeV

[5] This HEISTER 02I result is not actually an independent measurement of the absolute $\mu^+\nu_\mu$ branching fraction, but is in fact based on our $\phi\pi^+$ branching fraction of $3.6 \pm 0.9\%$, so it cannot be included in our overall fit. HEISTER 02I combines its $D_s^+ \to \tau^+\nu_\tau$ and $\mu^+\nu_\mu$ branching fractions to get $f_{D_s} = (285 \pm 19 \pm 40)$ MeV.

[6] BAI 95 uses one actual $D_s^+ \to \mu^+\nu_\mu$ event together with two $D_s^+ \to \tau^+\nu_\tau$ events and assumes μ-τ universality. This value of $\Gamma(\mu^+\nu_\mu)/\Gamma_{\text{total}}$ gives a pseudoscalar decay constant of $(430^{+150}_{-130} \pm 40)$ MeV.

[7] AOKI 93 assumes the ratio of production cross sections of the D_s^+ and D^0 is 0.27. The value of $\Gamma(\mu^+\nu_\mu)/\Gamma_{\text{total}}$ gives a pseudoscalar decay constant $f_{D_s} = (232 \pm 45 \pm 52)$ MeV.

[8] AUBERT 83 assume that the $D_s^\pm$ production rate is 20% of total charm production rate.

$\Gamma(\mu^+\nu_\mu)/\Gamma(\phi\pi^+)$ Γ_7/Γ_{15}

[26] ARTUSO 96 uses partially reconstructed $\overline{B}{}^0\to D^{*+}D_s^{*-}$ decays to get a model-independent value for $\Gamma(D_s^-\to\phi\pi^-)/\Gamma(D^0\to K^-\pi^+)$ of 0.92 ± 0.20 ± 0.11.
[27] BAI 95C uses $e^+e^-\to D_s^+D_s^-$ events in which one or both of the $D_s^\pm$ are observed to obtain the first model-independent measurement of the $D_s^+\to\phi\pi^+$ branching fraction, without assumptions about $\sigma(D_s^\pm)$. However, with only two "doubly-tagged" events, the statistical error is very large. ADLER 90B used the same method to set a limit.
[28] BUTLER 94, FRABETTI 93G, ALBRECHT 91, ALEXANDER 90B, and ANJOS 90B measure the ratio $\Gamma(D_s^+\to\phi\ell^+\nu_\ell)/\Gamma(D_s^+\to\phi\pi^+)$, where $\ell=e$ and/or μ, and then use a theoretical calculation of the ratio of widths $\Gamma(D_s^+\to\phi\ell^+\nu_\ell)/\Gamma(D^+\to\overline{K}{}^{*0}\ell^+\nu)$. Not everyone uses the same value for this ratio.
[29] The two MUHEIM 94 values here are model-dependent calculations based on distinct data sets. The first uses measurements of the $D_2^*(2460)^0$ and $D_{s1}(2536)^+$, the second uses B-decay factorization and $\Gamma(D_s^+\to\mu^+\nu_\mu)/\Gamma(D_s^+\to\phi\ell^+\nu_\ell)$. A third calculation using the semileptonic width of $D_s^+\to\phi\ell^+\nu_\ell$ is not independent of other results listed here. Note also the upper limit, based on the sum of established D_s^+ branching ratios.
[30] ALVAREZ 90C relies on the Lund model to estimate the ratio of D_s^+ to D^+ cross sections.
[31] Values based on crude estimates of the $D_s^\pm$ production level. DERRICK 85B errors are statistical only.

D_s^{*+} DECAY MODES

D_s^{*-} modes are charge conjugates of the modes below.

	Mode	Fraction (Γ_i/Γ)
Γ_1	$D_s^+\gamma$	(94.2±2.5) %
Γ_2	$D_s^+\pi^0$	(5.8±2.5) %

CONSTRAINED FIT INFORMATION

An overall fit to a branching ratio uses 1 measurements and one constraint to determine 2 parameters. The overall fit has a $\chi^2 = 0.0$ for 0 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

B-particle organization

Many measurements of B decays involve admixtures of B hadrons. Previously we arbitrarily included such admixtures in the $B^\pm$ section, but because of their importance we have created two new sections: "$B^\pm/B^0$ Admixture" for $\Upsilon(4S)$ results and "$B^\pm/B^0/B_s^0$/b-baryon Admixture" for results at higher energies. Most inclusive decay branching fractions and χ_b at high energy are found in the Admixture sections. B^0-$\overline{B}^0$ mixing data are found in the B^0 section, while B_s^0-$\overline{B}_s^0$ mixing data and B-$\overline{B}$ mixing data for a B^0/B_s^0 admixture are found in the B_s^0 section. CP-violation data are found in the $B^\pm$, B^0, and $B^\pm$ B^0 Admixture sections. b-baryons are found near the end of the Baryon section. Recently, we also created a new section: "V_{cb} and V_{ub} CKM Matrix Elements."

The organization of the B sections is now as follows, where bullets indicate particle sections and brackets indicate reviews.

[Production and Decay of b-flavored Hadrons]
[A Short Note on HFAG Activities]

PRODUCTION AND DECAY OF *b*-FLAVORED HADRONS

Updated December 2003 by Y. Kwon (Yonsei University, Seoul, Korea).

In the summer of 2001—almost four decades after CP violation was first discovered in the decay of neutral kaons—the BABAR and Belle collaborations reported the first observation of CP violation in the B meson system [1,2]. The measurement of the CP-violation parameter $\sin 2\beta (= \sin 2\phi_1)$ [3] marks the culmination of a very significant experimental and theoretical program that started in 1973 when Kobayashi and Maskawa proposed their model of the quark mixing matrix. Other recent developments in the physics of B mesons include new results on penguin decays, improved measurements of rare hadronic B decays, as well as new determinations of the CKM matrix elements V_{cb} and V_{ub} [4,5].

The structure of this mini-review is organized as follows. First, we briefly update the results on b quark production and discuss the spectroscopy and the lifetimes of b-flavored hadrons. Then after a brief description of basic properties of B meson decays, we give a short description of the experimental results on CP violation in B meson decays. More details about formalism and implications of CP violations are described in a separate mini-review [6] in this *Review* . This review closes with a description and update on hadronic and rare decays of B mesons.

Production and spectroscopy: Elementary particles are characterized by their masses, lifetimes, and internal quantum numbers. The bound states with a $\overline{b}$ antiquark and a u or d quark are referred to as the B_d (B^0) and the B_u (B^+) mesons, respectively. The first excitation is called the B^* meson. B^{**} is the generic name for the four orbitally excited ($L = 1$) B-meson states that correspond to the P-wave mesons in the charm system, D^{**}. Mesons containing an s or a c quark are denoted B_s^0 and B_c^+, respectively.

Although the b quark was discovered in a fixed-target experiment at Fermilab in 1977, most of the experimental information on b-flavored hadrons has come from colliding-beam machines. Currently, experimental studies of b decay are performed at the $\Upsilon(4S)$ resonance near production threshold, as well as at higher energies in proton-antiproton collisions and Z decays. High-energy $p\overline{p}$ collisions at the Tevatron produce b-flavored hadrons with very large cross-section ($\sigma_{b\overline{b}} \sim 50\mu b$), but it is only possible to trigger on a very small fraction of the decays because of limited acceptance and large background.

The $b\bar{b}$ production cross-section at the Z and $\Upsilon(4S)$ resonances are about 6.6 nb and 1.1 nb, respectively.

By far the largest samples of B mesons have been collected by the e^+e^- collider detectors running at $\Upsilon(4S)$ ("B-Factories"). As of this writing, both Belle and BABAR have accumulated approximately 150 fb^{-1}. The $\Upsilon(4S)$ resonance decays only to $B^0\overline{B}^0$ and B^+B^- pairs, while at high-energy collider experiments, heavier states such as B_s^0 or B_c^+ mesons and b-flavored baryons are produced as well. The current experimental limit for non-$B\overline{B}$ decays of the $\Upsilon(4S)$ is less than 4% at the 95% confidence level (CL) [7]. The $\bar{b}$ (or b) quarks produced at high-energy collider experiments hadronize as B^0, B^+, B_s^0, and B_c^+ mesons (or their antiparticles), or as baryons containing $\bar{b}$ (or b) quarks.

For quantitative studies of B decays, the initial composition of the data sample must be known. In particular, the ratio f_+/f_0 of charged to neutral $\Upsilon(4S)$ decays is crucial to calculate the decay branching fractions for B-factory experiments. CLEO and BABAR have measured the ratio $(f_+/f_0)(\tau_+/\tau_0)$ with exclusive $B \to \psi K^{(*)}$ [8,9] and $B \to D^*\ell\nu$ [10] decays, where τ_+/τ_0 is the B^+/B^0 lifetime ratio (*see next section*). By using the world-average value of τ_+ and τ_0 Belle also extracted the value of f_+/f_0 [11]. Using the current average of τ_+/τ_0, the average becomes $f_+/f_0 = 1.044 \pm 0.050$ [12]. This is consistent with equal production of B^+B^- and $B^0\overline{B}^0$ pairs, and unless explicitly stated otherwise, we will assume $f_+/f_0 = 1$. This assumption is further supported by the near equality of the B^+ and B^0 masses. Again using exclusive $B \to J/\psi K^{(*)}$ decays, CLEO determined these masses to $m(B^0) = 5.2791 \pm 0.0007 \pm 0.0003$ GeV/c^2 and $m(B^+) = 5.2791 \pm 0.0004 \pm 0.0004$ GeV/c^2, respectively [13].

More diverse species of b-flavored hadrons are produced in the experiments at the Z resonance and in the high-energy $p\overline{p}$ collisions. Table 1 shows the fractions f_d, f_u, f_s, and $f_{\rm baryon}$ of B^0, B^+, B_s^0, and b baryons in an unbiased sample of weakly decaying b hadrons produced at the Z resonance and in $p\overline{p}$ collisions [12]. A detailed account can be found elsewhere in this *Review* [14]. The values assume identical hadronization in $p\overline{p}$ collisions and in Z decay, even though these could, in principle, differ because of the different momentum distributions of the b–quark in these processes.

Table 1: Fractions of weakly decaying b-hadron species in $Z \to b\bar{b}$ decay and in $p\overline{p}$ collisions at $\sqrt{s} = 1.8$ TeV.

b hadron	Fraction [%]
B^+, B^0	39.7 ± 1.0
B_s^0	10.7 ± 1.1
b baryons	9.9 ± 1.7

To date, the existence of several b-flavored mesons (B^+, B^0, B_s^0, B_c^+, and various excitations), as well as the Λ_b baryon has been established. Using exclusive hadronic decays such as $B_s^0 \to J/\psi\phi$ and $\Lambda_b \to J/\psi\Lambda$, the masses of these states are now known with the precision of a few MeV. The current world averages of the B_s^0 and the Λ_b mass are 5.3696 ± 0.0024 GeV/c^2 and 5.624 ± 0.009 GeV/c^2, respectively. Clear evidence for the B_c^+, the last weakly decaying bottom meson, has been published by CDF [15]. They reconstruct the semileptonic decay $B_c^+ \to J/\psi\ell X$, and extract a B_c^+ mass of $6.40 \pm 0.39 \pm 0.13$ GeV/c^2. First indications of Ξ_b production have been presented by the LEP Collaborations [16,17].

Excited B-meson states have been observed by CLEO, LEP, CUSB, and CDF. The current world average of the B^*–B mass difference is 45.78 ± 0.35 MeV/c^2. Evidence for B^{**} production has been presented by the LEP and CDF experiments [18]. Inclusively reconstructing a bottom hadron candidate combined with a charged pion from the primary vertex, they see the B^{**} as a broad resonance around 5.697 ± 0.009 GeV/c^2 in the $M(B\pi) - M(B)$ mass distribution [19]. Due to the inclusive approach, the mass resolution is limited to about 40 MeV, which makes it very difficult to identify the narrow states, B_1^* and B_2^*, separately. The LEP experiments have also provided evidence for excited B_s^{**} states.

Lifetimes: Precise lifetimes are key in extracting the weak parameters that are important for understanding the role of the CKM matrix in CP violation, such as the determination of V_{cb} and $B_s^0\overline{B}_s^0$ mixing measurements. In the naive spectator model, the heavy quark can decay only via the external spectator mechanism, and thus, the lifetimes of all mesons and baryons containing b quarks would be equal. Nonspectator effects, such as the interference between contributing amplitudes, modify this simple picture and give rise to a lifetime hierarchy for b-flavored hadrons similar to the one in the charm sector. However, since the lifetime differences are expected to scale as $1/m_Q^2$, where m_Q is the mass of the heavy quark, the variation in the b system should be significantly smaller, of order 10% or less [20]. For the b system we expect

$$\tau(B^+) \geq \tau(B^0) \approx \tau(B_s^0) > \tau(\Lambda_b^0) \gg \tau(B_c^+) . \quad (1)$$

In the B_c^+, both quarks can decay weakly, resulting in its much shorter lifetime. Measurements of lifetimes for the various b-flavored hadrons thus provide a means to determine the importance of non-spectator mechanisms in the b sector.

Over the past years, advanced algorithms based on impact parameter or decay length measurements exploiting the potential of silicon vertex detectors resulted in improvement of lifetime measurements. However, in order to reach the precision necessary to test theoretical predictions, the results from different experiments need to be averaged. This is a challenging task that requires detailed knowledge of common systematic uncertainties, and correlations between the results from different experiments. The average lifetimes for b-flavored hadrons

given in this edition have been determined by the Heavy Flavor Averaging Group (HFAG) [12]. A detailed description of the procedures and the treatment of correlated and uncorrelated errors can be found in [21]. The asymmetric B factories are now making significant contributions to the B^+ and B^0 lifetime measurements. Their use of fully–reconstructed B decays yield measurements with much reduced statistical and systematic uncertainties. The measurements are free, for example, from systematics associated with modelling of fragmentation. The new world average b-hadron lifetimes are summarized in Table 2.

Table 2: Summary of inclusive and exclusive b-hadron lifetime measurements.

Particle	Lifetime [ps]
B^0	1.536 ± 0.014
B^+	1.671 ± 0.018
B_s^0	1.461 ± 0.057
B_c^+	$0.46^{+0.18}_{-0.16} \pm 0.03$
b baryon	1.208 ± 0.051
Λ_b	1.229 ± 0.080
Ξ_b	$1.39^{+0.34}_{-0.28}$
b hadron	1.564 ± 0.014

For comparison with theory, lifetime ratios are preferred. Experimentally we find

$$\frac{\tau_{B^+}}{\tau_{B^0}} = 1.086 \pm 0.017\,, \quad \frac{\tau_{B_s^0}}{\tau_{B^0}} = 0.951 \pm 0.038\,,$$

$$\frac{\tau_{\Lambda_b}}{\tau_{B^0}} = 0.800 \pm 0.053\,,$$

while theory makes the following predictions [22]

$$\frac{\tau_{B^+}}{\tau_{B^0}} = 1 + 0.05 \left(\frac{f_B}{200\ \text{MeV}}\right)^2\,, \quad \frac{\tau_{B_s^0}}{\tau_{B^0}} = 1 \pm 0.01\,, \quad \frac{\tau_{\Lambda_b}}{\tau_{B^0}} = 0.9\ .$$

In conclusion, the pattern of measured B-meson lifetimes follows the theoretical expectations, and non-spectator effects are observed to be small. The short B_c^+ lifetime has been predicted correctly. However, the Λ_b-baryon lifetime may be somewhat smaller than expected. As has been noted by several authors, the observed value of the Λ_b lifetime is difficult to accommodate theoretically [23–29].

Similar to the kaon system, neutral B mesons contain short- and long-lived components. The Standard Model predicts that the lifetime difference is significantly smaller. The most stringent limit on the lifetime difference of neutral B_d mesons is recently obtained by BABAR: $-0.156 < \Delta\Gamma_d/\Gamma_d < 0.042$ at 90% CL [30] where $\Delta\Gamma_d \equiv \Gamma_H - \Gamma_L$ with $\Gamma_H(\Gamma_L)$ being the decay width of the heavier (lighter) B_d meson. They measure the time-dependence of $\Upsilon(4S)$ decays where one neutral B is fully reconstructed and the other B is identified as being either B^0 or $\overline{B}^0$. In this analysis, possible violations in CP, T, and CPT are fully considered. The limit on the lifetime difference for B_s^0 is $|\Delta\Gamma_s|/\Gamma_s < 0.54$ at 95% CL. This result is based on a combination [12] of the various B_s^0 proper time measurements. A more restrictive limit for the B_s^0 system ($|\Delta\Gamma_s|/\Gamma_s < 0.29$) can be obtained if one assumes $\Gamma_s = \Gamma_d$.

***B* meson decay properties:** B^+ and B^0 mesons are the lightest elements of the b-flavored hadrons, hence they decay via weak interactions. Since the mass of a b-quark is much larger than its partner quark (d or u), B meson decays are mostly described by the decay of the b quark ("spectator model"). The dominant decay mode of a b-quark is $b \to cW^*$ where the virtual W^* eventually materializes either into a pair of leptons, $\ell\nu$ ("semileptonic decay") or into a pair of quarks which then hadronizes. The decays in which the spectator quark combines with one of the quarks from W^* are suppressed because the colors of the quarks from different sources must match ("color-suppression").

Couplings of quarks to the W boson are described by the Cabibbo-Kobayashi-Maskawa (CKM) matrix. The regular pattern of the three lepton and quark families is one of the most intriguing puzzles in particle physics. The existence of families gives rise to many of the free parameters in the Standard Model, in particular the fermion masses, and the elements of the CKM matrix. In the Standard Model (SM) of three generations, the CKM matrix is parameterized by three real parameters and one complex phase. This complex phase can become a source of CP violations in B meson decays. A more detailed discussion of the CKM matrix and CP violation can be found elsewhere in this *Review* [6,31].

Semileptonic B decays $B \to X_c\ell\nu$ and $B \to X_u\ell\nu$ provide an excellent laboratory to measure CKM elements $|V_{cb}|$ and $|V_{ub}|$ respectively, because the strong interaction effects are much simplified due to the two leptons in the final state. Both exclusive decays and inclusive decays can be used and the nature of uncertainties are quite complimentary. For exclusive decay analysis a knowledge about the form factors for the exclusive hadronic system $X_{c(u)}$ is required. For inclusive analysis, it is usually required to restrict the available phase-space of the decay products to suppress backgrounds; subsequently uncertainties are introduced in the extrapolation to the full phase-space. Moreover, restriction to a small corner of the phase-space may result in break-down of the operator product expansion scheme, thus making theoretical calculations unreliable. A more detailed discussion of the B semileptonic decays and extraction of $|V_{cb}|$ and $|V_{ub}|$ are described elsewhere in the *Review* [4,5].

On the other hand, hadronic decays of B are complicated because of strong interaction effects caused by the surrounding cloud of light quarks and gluons. While this complicates the extraction of CKM matrix elements, it also provides a great opportunity to study perturbative and non-perturbative QCD, hadronization, and Final State Interaction (FSI) effects, etc.

Other (non-spectator) decay processes include W-exchange and annihilation decays both of which occur at tree level processes. Higher-order loop-induced flavor-changing neutral current (FCNC) decay processes ("Penguin decays") are also available. In the Standard Model, these decays are much suppressed

in comparison to the spectator decays. Penguin decays are experimentally established by observations of $B \to K^*\gamma$ and recently $B \to K^{(*)}\ell^+\ell^-$. Some observed decay modes such as $B^0 \to D_s^- K^+$ may be interpreted as a W-exchange process. There has not been any experimental evidence for annihilation decays of B.

Experimental results on CP violation in B decays: The determination of all the parameters of the CKM matrix is required to fully define the Standard Model, and is central to the experimental program in heavy-flavor physics. In the framework of the Standard Model, the CKM matrix must be unitary, *i.e.* $VV^\dagger = 1$. This gives rise to relationships between the matrix elements that can be visualized as triangles in the complex plane, for example

$$V_{ub}^* V_{ud} + V_{cb}^* V_{cd} + V_{tb}^* V_{td} = 0\,.$$

The interior angles of the triangle can be expressed in terms of the CKM elements

$$\alpha = \phi_2 = arg(-\frac{V_{ud}V_{ub}^*}{V_{td}V_{tb}^*})\,,$$

$$\beta = \phi_1 = arg(-\frac{V_{cd}V_{cb}^*}{V_{td}V_{tb}^*})\,,$$

$$\gamma = \phi_3 = arg(-\frac{V_{cd}V_{cb}^*}{V_{ud}V_{ub}^*})\,.$$

The most precise measurements of the angle β have come from the two energy-asymmetric B-factories running at $\Upsilon(4S)$, KEKB and PEP-II, by analyzing time-dependent CP asymmetries in $b \to c\bar{c}s$ decay modes including $B \to J/\psi K_S$. Given the tiny boost the B mesons receive in the $\Upsilon(4S)$ rest frame, asymmetric beam energies are required to improve the precision of time-dependence measurement. At KEKB, for example, the boost is $\beta\gamma = 0.43$, and the typical B meson decay length is dilated from $\approx 20\ \mu m$ to $\approx 200\ \mu m$. PEP-II uses a slightly larger boost, $\beta\gamma = 0.55$.

In the decay chain $\Upsilon(4S) \to B^0\overline{B}^0 \to f_{CP} f_{\rm tag}$, in which one of the B mesons decays at time t_{CP} to f_{CP} and the other decays at time $t_{\rm tag}$ to a final state $f_{\rm tag}$ that distinguishes between B^0 and $\overline{B}^0$, the decay rate has a time dependence given by [6]

$$\mathcal{P}^q_{f_{CP}}(\Delta t) = \frac{e^{-|\Delta t|/\tau}}{4\tau}\left[1 + q\cdot\{S\sin(\Delta m_d \Delta t) - C\cos(\Delta m_d \Delta t)\}\right],$$

where τ is the B^0 lifetime, Δm_d is the mass difference between the two B^0 mass eigenstates, and $\Delta t = t_{CP} - t_{\rm tag}$. The parameter q is determined by identifying the b-quark flavor of the accompanying B meson ("flavor tagging") using inclusive features of the charged particles in $f_{\rm tag}$. For instance, $q = +1(-1)$ when the tagging B meson is a B^0 ($\overline{B}^0$). The CP-violating parameters S and C are expressed as

$$C = \frac{1-|\lambda|^2}{1+|\lambda|^2}, \qquad S = \frac{2Im\lambda}{1+|\lambda|^2},$$

where λ is a complex parameter that depends on both B^0-$\overline{B}^0$ mixing and on the amplitudes for B^0 and $\overline{B}^0$ decay to f_{CP}. In the SM, to a good approximation, $|\lambda|$ is equal to the absolute value of the ratio of the $\overline{B}^0$ to B^0 decay amplitudes. In the absence of direct CP violation, $|\lambda| = 1$. For $b \to c\bar{c}s$ transition, the SM predicts $S = -\xi \sin 2\beta$, where $\xi = +1(-1)$ for CP-even (-odd) final states, and $C = 0$.

In the summer of 2001, both BABAR [1] and Belle [2] reported first significant measurements of $\sin 2\beta$, thereby establishing CP violation in the B^0 meson decays. Both experiments have updated their results recently. Using a data sample of 88 million $B\overline{B}$ pairs, BABAR [32] obtained $\sin 2\beta = 0.741 \pm 0.067 \pm 0.034$, while with 152 million $B\overline{B}$ pairs, Belle [33] reported $\sin 2\beta = 0.733 \pm 0.057 \pm 0.028$. Averaging the latest results from the two experiments we find

$$\sin 2\beta = \sin 2\phi_1 = 0.736 \pm 0.049.$$

This value is consistent with CKM expectations.

Charmless B decays mediated by the $b \to s$ penguin transition are potentially sensitive to new CP-violating phases from physics beyond the SM [34]. In the SM, measurement of S in the $b \to s\bar{s}s$ transition should yield approximately the same value ($-\xi \sin 2\beta$) as in the $b \to c\bar{c}s$ modes. Both BABAR and Belle measured S for $B \to \eta' K_S$ and ϕK_S. Both final states are CP-odd ($\xi = -1$). Belle also measured S for $B \to K^+K^-K_S$ (non-resonant). From an angular analysis, Belle concludes that $K^+K^-K_S$ is primarily CP-even [35]. The average value of effective $\sin 2\beta (\equiv \sin 2\beta_{\rm eff})$ for $b \to s$ penguin transitions calculated by HFAG is 0.24 ± 0.15 where the error is dominantly statistical. The largest deviation from $b \to c\bar{c}s$ result ($\sin 2\beta = 0.736$) comes from Belle's $B \to \phi K_S$ mode where they measure $\sin 2\beta_{\rm eff} = -0.96 \pm 0.50^{+0.09}_{-0.11}$. For the same mode, BABAR measures $\sin 2\beta_{\rm eff} = +0.45 \pm 0.43 \pm 0.07$. There is a 2.1 σ discrepancy between Belle and BABAR.

Experimental work on the determination of the other two angles of the unitarity triangle is also underway. Much larger data samples will be needed to obtain precision results and to challenge the Standard Model. Information on $\sin 2\alpha$ can be extracted from $B \to \pi^+\pi^-$ decays following a procedure similar to the one outlined above. Unfortunately, these decays suffer from fairly small branching fractions ($\mathcal{O}(10^{-6})$) and sizeable contributions from penguin diagrams that complicate the extraction of the CP phases. Because of this, the time-dependent asymmetry in $B \to \pi^+\pi^-$ will not be proportional to $\sin\alpha$, but to $\sin 2\alpha_{\rm eff}$, with an unknown correction to α. Despite these difficulties, attempts to measure CP asymmetries in the $\pi^+\pi^-$ mode have been reported. Using 113 fb^{-1}, BABAR [36] extracts $S(= \sqrt{1-C^2} \times \sin 2\alpha_{\rm eff}) = -0.40 \pm 0.22 \pm 0.03$ and Belle [37] finds $S = -1.23 \pm 0.41^{+0.08}_{-0.07}$ with 78 fb^{-1}. The contribution from direct CP violation in the $B \to \pi^+\pi^-$ decay shows up as a nonzero amplitude C. Both experiments have determined C simultaneously with S. BABAR finds $C = -0.19 \pm 0.19 \pm 0.05$, while Belle measures $C = -0.77 \pm 0.27 \pm 0.08$. BABAR also measured CP-violation parameters in the related mode $B^0 \to \rho^\pm\pi^\mp$ and obtained $S_{\rho\pi} = -0.13 \pm 0.18 \pm 0.04$ and $C_{\rho\pi} = 0.35 \pm 0.13 \pm 0.05$ [38].

The time- and flavor-integrated charge asymmetry $A_{CP}^{\rho\pi}$ is also measured as $-0.114 \pm 0.062 \pm 0.027$. The decay $B^0 \to \rho^+\rho^-$ is another promising mode for measuring α and has the advantage of a larger expected decay rate and smaller uncertainty in penguin contaminations. Based on the recent limit on $B^0 \to \rho^0\rho^0$ and the measurements of $B^+ \to \rho^+\rho^0$ branching fraction [79], BABAR sets an upper limit on the penguin pollution to $B^0 \to \rho^+\rho^-$ [81].

Several methods have been suggested to measure the third angle, $\gamma \approx \arg(V_{ub})$ [39]. However, they require very large data samples (such as for $B \to DK$), measurements of B_s^0 decays or suffer from large theoretical uncertainties, rendering γ particularly difficult to measure.

Gronau and Wyler [40] first suggested that decays of the type $B \to DK$ can be used to extract the angle γ. An example of such Cabibbo–suppressed modes, $B^- \to D^0K^-$ was first observed by CLEO [41] and later confirmed by Belle [42] and BABAR [43]. By selecting CP eigenstates for the D^0 meson decay mode, both Belle and BABAR have limited direct CP violation in these decays [43,44].

The decay amplitudes for $B^+ \to D^0K^+$ and $B^+ \to \overline{D}^0K^+$ can interfere if the D^0 and $\overline{D}^0$ decay to a common final state, such as $K_S\pi^+\pi^-$. Since the Cabibbo-suppressed $B^+ \to D^0K^+$ amplitude involves V_{ub}, the phase difference measures the angle γ. Belle made a preliminary attempt of a $D^0 \to K_S\pi^+\pi^-$ Dalitz plot analysis for this channel to simultaneously determine γ and an unknown strong phase [45].

The Cabibbo-favoured $B^0 \to D^{(*)-}\pi^+$ amplitude can have interference with the doubly Cabibbo-suppressed amplitude of $\overline{B}^0 \to D^{(*)-}\pi^+$. The relative weak phase between these two amplitudes is γ and, when combined with the $B^0\overline{B}^0$ mixing phase, the total phase difference is $-(2\beta+\gamma)$. Therefore $B^0 \to D^{(*)\pm}\pi^\mp$ decays can provide sensitivity to γ. The interpretation of the observables in terms of unitarity angles requires external input on the ratio of magnitude of the two amplitudes. Due to the disparate strength of the two interfering amplitudes, CP asymmetry is expected to be small, hence the possible occurrence of CP violation on the tag side may become an important obstacle. Preliminary results on measuring the CP-violating amplitudes in the partially and fully reconstructed $B^0 \to D^{(*)\pm}\pi^\mp$ decays have been made by BABAR [46,47] and Belle [48].

Hadronic B decays: The experimental results on hadronic B decays have steadily improved over the past years and the measurements have reached a sufficient precision to challenge our understanding of the dynamics of these decays. It has been suggested that in analogy to semileptonic decays, two-body hadronic decays of B mesons can be expressed as the product of two independent hadronic currents, one describing the formation of a charm meson, and the other the hadronization of the remaining $\overline{u}d$ (or $\overline{c}s$) system from the virtual W^-. Qualitatively, for a B decay with a large energy release, the $\overline{u}d$ pair, which is produced as a color singlet, travels fast enough to leave the interaction region without influencing the second hadron formed from the c quark and the spectator antiquark. The assumption that the amplitude can be expressed as the product of two hadronic currents is called "factorization" in this paper. Recent theoretical work has provided a more solid foundation for this hypothesis [49,50].

With a good neutral particle detection and hadron identification capabilities of B-factory detectors, a substantial fraction of hadronic B decay events can be fully reconstructed. Because of the kinematic constraint of $\Upsilon(4S)$, the energy sum of the final-state particles of a B meson decay is always equal to one half of the total energy in the center of mass frame. As a result, the two variables, ΔE (energy difference) and M_B (B candidate mass with a beam-energy constraint) are very effective to suppress combinatorial background both from $\Upsilon(4S)$ and $e^+e^- \to q\bar{q}$ continuum events. In particular, the energy-constraint in M_B improves the signal resolution by almost an order of magnitude.

Such a kinematically clean environment of B meson decays provides a very nice laboratory to search for new states. For instance, quark-level $b \to c\bar{c}s$ decays have been used to search for new charmonium and charm-strange mesons and study their properties in detail. Recently, BABAR discovered a new narrow charm-strange state $D_{sJ}(2317)$ [51] and CLEO observed a similar state $D_{sJ}(2460)$ [52]. But the properties of these new states were largely unknown. Belle later observed $B \to DD_{sJ}(2317)$ and $B \to DD_{sJ}(2460)$, which helped identify some quantum numbers of $D_{sJ}(2460)$ [53].

In the $B \to$ charmonium mode, several new modes have been added. In particular, Belle studied $B \to \{J/\psi\pi^+\pi^-\}K^+$ decays and looked for new states that decay to $J/\psi\pi^+\pi^-$. A new very narrow state was discovered at 3.872 GeV which approximately coincides with the sum of D^0 and D^{*0} masses [54]. This state was also confirmed by CDF [55]. The detailed properties of this new state are not known yet.

Most branching fractions for exclusive $B \to J/\psi K^{(*)}$ transitions are updated. Being a vector-vector final state, the CP eigenvalue of $J/\psi K^*$ depends on its polarization state. Therefore, the polarization needs to be measured in order to extract CP violation parameters from this decay. Updated measurements of the polarization in $B \to J/\psi K^*$ have been made by Belle, BABAR, CDF and CLEO and an outstanding discrepancy between theory and experiment [56] is resolved. The decay amplitudes for $B \to \phi K^*$ are also measured and the fraction of longitudinal polarization is $0.41 \pm 0.10 \pm 0.04$ [57].

$B^0 \to D^{(*)+}D^{(*)-}$ decays are also sensitive to the CKM unitarity angle β. However, the theoretically uncertain penguin contribution with different weak phases may shift the observed asymmetry by an amount that depends on the penguin/tree ratio. This shift is expected to be small in models based on factorization and heavy-quark symmetry. $B^0 \to D^{*+}D^{*-}$ decays have been observed by CLEO [58] and BABAR [59] with an average branching fraction of $(8.7 \pm 1.8) \times 10^{-4}$. By studying the polarization of this mode, BABAR determines the CP-odd

fraction as $0.063 \pm 0.055 \pm 0.09$ as well as the CP-violating parameter $Im(\lambda) = 0.05 \pm 0.29 \pm 0.10$ [60] which the SM predicts to be $-\sin 2\beta$ in the absence of penguin contamination. $B^0 \to D^{*-}D^+$ decay is first observed by Belle [61] and confirmed by BABAR [62]. The average branching fraction for this mode is $(9.3 \pm 1.5) \times 10^{-4}$. BABAR also set bounds on the CP-violating parameters for this mode.

Angular distributions have been studied for other B decays to two vector mesons, in $B \to D^*\rho$ [63] and $B \to D^*D_s^*$ [64,65]. These results can be used to test the factorization hypothesis as suggested by Körner and Goldstein [66] by comparing exclusive hadronic B decays to the corresponding semileptonic modes. For certain $b \to c$ decays with large energy release it is expected that factorization works well. An example is given by the longitudinal polarization of ρ mesons in $B \to D^*\rho$ decays. CLEO's result of $\Gamma_L/\Gamma = 0.885 \pm 0.016 \pm 0.012$ [63] agrees well with the factorization expectation, 0.85 – 0.88 [67–70]. Within the experimental precision (10 – 30%) and over the limited q^2 range ($\sim M_\rho^2$) probed so far, the measurements agree with factorization predictions. The average fraction of longitudinal polarization for $B \to D^*D_s^*$ is determined as 0.52 ± 0.05 which is again consistent with predictions based on factorization.

The $B^0 \to \overline{D}^{(*)0}h^0$ decay modes, where h^0 is a light neutral meson, are expected to proceed via an internal spectator diagram and to be color-suppressed relative to external spectator decays such as $B^0 \to \overline{D}^{(*)-}\pi^+$. The contribution of the W-exchange diagram is usually assumed to be negligible [71]. In the charm meson decays, the effect of color suppression is obscured by effects of final state interactions, or reduced by non-factorizable contributions. Color suppression is, however, believed to be operative in the B meson system. Until recently, the $B \to$ charmonium transitions were the only identified color-suppressed B decays. Belle, CLEO and BABAR have now reported the observations of $B^0 \to \overline{D}^0\pi^0$ and $D^{*0}\pi^0$ [73–74]. Belle and BABAR also observed many other color-suppressed modes including $B^0 \to D^0\rho^0$ [75], $B^0 \to D^0\eta$, $D^0\omega$ [74,75] and $B^0 \to D^{*0}\eta$, $D^{*0}\omega$ [74]. The measured branching fractions are consistently higher than recent theoretical predictions based on naive factorization hypothesis [71]. Combining these results with previous measurements of other $B \to D^{(*)}\pi$ final states, it is possible to extract the strong interaction phase δ_I between the isospin 1/2 and 3/2 amplitudes in the $D\pi$ and $D^*\pi$ final states. The results from all three experiments are consistent with δ_I being approximately 30°. These results suggest the possibility of significant nonfactorizable effects such as final-state re-scattering.

The decay $B^0 \to D_s^- K^+$ is expected to occur either via a W exchange diagram or via final-state rescattering process. Because of uncertainties in final-state interaction effects, predictions for its branching fraction vary over a wide range. Therefore measurement of this decay can provide a useful probe of B decay dynamics. Belle [82] observed this decay and BABAR [83] also found an evidence for it. The average branching fraction is $\mathrm{B}(B^0 \to D_s^- K^+) = (3.8 \pm 1.3) \times 10^{-5}$.

Rare B decays: All B-meson decays that do not occur through the usual $b \to c$ transition are known as rare B decays. These include both semileptonic and hadronic $b \to u$ decays that are suppressed at leading order by the small CKM matrix element V_{ub}, as well as higher order processes such as electromagnetic and gluonic penguin decays.

Charmless B meson decays into two-body hadronic final states such as $B \to \pi\pi$ and $K\pi$ are experimentally clean and provide good opportunities to probe new physics and search for indirect and direct CP violations. The final state particles in these decays tend to have larger momenta than average B decay products, therefore the event environment is cleaner than $b \to c$ decays. Over the past years, many such modes have been observed by BABAR, Belle and CLEO. Branching fractions are typically around 10^{-5}, for exclusive channels. Because of high-momenta for final state particles, the dominant source of background is from $e^+e^- \to q\bar{q}$ continuum events and sophisticated background suppression techniques exploiting the event shape variables are essential for these analyses. The results are in general consistent between the three experiments and confirm the larger than expected rate for gluonic penguin decays such as $B \to K\pi$.

Several rare decay modes such as $B^0 \to K^+\pi^-$ have contributions from both $b \to u$ tree diagram and $b \to sg$ penguin diagram processes. If the size of each contribution is comparable to each other, the interference between them may cause direct CP violation which may show up as a charge asymmetry in time-independent decay rate measurement. The average charge asymmetry in the $K^+\pi^-$ mode is -0.095 ± 0.028 [12]. No clear evidence for direct CP violation have been found in other modes.

The fact that $B^0 \to \pi^+\pi^-$ also can have interference between tree and penguin processes makes it difficult to extract a unitarity angle α from time-dependent CP asymmetry measurements. In order to extract α unambiguously, an isospin analysis has been suggested [76]. A crucial element for the isospin analysis is a flavor-specific measurement of $B^0 \to \pi^0\pi^0$ and $\overline{B}^0 \to \pi^0\pi^0$. Recently BABAR observed the $B^0 \to \pi^0\pi^0$ decays and measured the flavor-averaged branching fraction $\mathrm{B}(B^0 \to \pi^0\pi^0) = (2.1 \pm 0.6 \pm 0.3) \times 10^{-6}$ [77]. Belle also reported evidence for the same mode and measured the flavor-averaged branching fraction $(1.7 \pm 0.6 \pm 0.2) \times 10^{-6}$ [78]. The decays $B \to \rho\rho$ are also expected to provide important information on CP violation. Both BABAR [79] and Belle [80] have observed $B^+ \to \rho^+\rho^0$ and measured its polarization. BABAR have observed $B^0 \to \rho^+\rho^-$ and measured its polarization as well [81].

The decay $B^0 \to D_s^+\pi^-$ proceeds via $b \to u$ tree diagram where D_s is produced from the vertex of virtual W hadronization. Therefore, it is sensitive to $|V_{ub}|$, although actual extraction of $|V_{ub}|$ becomes obscured by unknown non-factorizable strong-interaction effects. Both Belle [82] and BABAR [83] found evidences for this mode, and the average branching fraction is $\mathrm{B}(B^0 \to D_s^+\pi^-) = (2.7 \pm 1.0) \times 10^{-5}$.

Electroweak penguin decays:

The observation of the decay $B \to K^*(892)\gamma$, reported in 1993 by the CLEO experiment, provided first evidence for the one-loop FCNC penguin diagram [84]. Using larger data samples, CLEO, Belle and BABAR have updated this analysis and have added several new decay modes such as $B \to K_2^*(1430)\gamma$. So far no evidence for the decays $B \to \rho\gamma$ and $B \to \omega\gamma$ has been found. BABAR obtained the most stringent upper limit for the ratio $\mathrm{B}(B \to (\rho/\omega)\gamma)/\mathrm{B}(B \to K^*\gamma) < 0.047$ at 90% CL [85]. The limit on the ratio of branching fractions implies that $|V_{td}/V_{ts}| < 0.34$ at 90% CL.

The observed branching fractions were used to constrain a large class of Standard Model extensions [86]. However, due to the uncertainties in the hadronization, only the inclusive $b \to s\gamma$ rate can be reliably compared with theoretical calculations. This rate can be measured from the endpoint of the inclusive photon spectrum in B decay. The current PDG average of the CLEO [87] and the Belle [88] measurements for the B meson is $\mathrm{B}(B \to X_s\gamma) = (3.3 \pm 0.4) \times 10^{-4}$. Consistent results have been reported by ALEPH for inclusive b–hadrons produced at the Z. The measured branching fraction can be compared to recent theoretical calculations by Chetyrkin, Misiak, Munz and by Kagan and Neubert which predict $\mathrm{B}(b \to s\gamma) = (3.29 \pm 0.33) \times 10^{-4}$ [89–91].

According to the SM, the CP asymmetry in $b \to s\gamma$ is smaller than 1 %, but some non-SM models allow significanly larger CP asymmetry (~ 10 %) without altering the inclusive branching fraction [92–94]. CLEO has searched for CP violation in this mode, and set a range on $A_{CP}(b \to s\gamma)$ at 90 % CL as $-0.27 < A_{CP} < 0.10$ [95]. Belle also set a preliminary range as $-0.107 < A_{CP} < 0.099$ at 90 % CL [96]. CP asymmetry in the exclusive $B \to K^*\gamma$ mode is also searched for by CLEO [97] and BABAR [98]. The PDG average of the asymmetry is $A_{CP}(B \to K^*\gamma) = -0.01 \pm 0.07$.

In addition, CLEO has measured the inclusive photon energy spectrum for $b \to s\gamma$ [99]. Analyzing the shape of the spectrum they obtained the first and second moment for photon energies above 2 GeV:

$$< E_\gamma >= 2.346 \pm 0.032 \pm 0.011 \text{ GeV} \qquad (2)$$

and

$$< E_\gamma^2 > - < E_\gamma >^2 = 0.0226 \pm 0.0066 \pm 0.0020 \text{ GeV}^2 . \qquad (3)$$

These results can be used to extract non-perturbative HQET parameters that are needed for the determination of the CKM matrix element V_{ub}.

Additional information on FCNC processes can be obtained from $B \to X_s\ell^+\ell^-$ decays which are mediated by electroweak penguin and W-box diagrams. Exclusive $B \to K\ell^+\ell^-$ decay was first observed by Belle [100]. Recently, both BABAR [101] and Belle [102] updated the measurments and the PDG average of the branching fraction is

$$\mathrm{B}(B \to K\ell^+\ell^-) = (0.54 \pm 0.08) \times 10^{-6}.$$

The branching fraction for $B \to K^*(892)\ell^+\ell^-$ is also measured by both experiments and the average value is

$$\mathrm{B}(B \to K^*\ell^+\ell^-) = (1.05 \pm 0.20) \times 10^{-6}.$$

The branching fraction of inclusive $B \to X_s\ell^+\ell^-$ decays is measured by Belle [103]:

$$\mathrm{B}(B \to X_s\ell^+\ell^-) = (6.1 \pm 1.4^{+1.4}_{-1.1}) \times 10^{-6}.$$

These results are consistent with SM expectations.

Summary and Outlook: The study of B mesons continues to be one of the most productive fields in particle physics. CP violation has been observed for the first time outside the kaon system. Many hadronic $b \to u$ transitions and gluonic penguin decays have been observed, and the emerging pattern is still full of surprises. The coming years look equally promising. Each of the asymmetric B-factory experiments, Belle and BABAR, has accumulated data samples well over 100 fb^{-1}. Run II at Fermilab has begun and new results from CDF and D0 can be expected soon. These experiments promise a rich spectrum of rare and precision measurements that have the potential to affect fundamentally our understanding of the Standard Model and CP-violating phenomena.

A NOTE ON HFAG ACTIVITIES

Written December 2003 D. Kirkby (UC, Irvine) and Y. Sakai (KEK).

The Heavy Flavor Averaging Group (HFAG) has been formed, continuing the activities of LEP Heavy Flavor Steering group, to provide the averages for measurements dedicated to the b-flavor related quantities. The HFAG consists of representatives and contacts from the experimental groups: BaBar, Belle, CDF, CLEO, DØ , LEP, and SLD.

In the averaging, the input parameters used in the various analyses are adjusted (rescaled) to common values, and all known correlations are taking into account. The HFAG provides averages for b-hadron lifetimes, B-oscillation parameters, semileptonic parameters, rare decay branching fractions, and CP-violation measurements. The averages provided by the HFAG are listed as "OUR EVALUATION" with a note mentioning about it.

The complete listing of averages and more detailed information on the averaging are available at;

http://www.slac.stanford.edu/xorg/hfag and also at http://belle.kek.jp/mirror/hfag (KEK mirror site).

$B^{\pm}$

$I(J^P) = \frac{1}{2}(0^-)$

Quantum numbers not measured. Values shown are quark-model predictions.

See also the $B^{\pm}/B^0$ ADMIXTURE and $B^{\pm}/B^0/B_s^0/b$-baryon ADMIXTURE sections.

$B^{\pm}$ MASS

The fit uses m_{B^+}, $(m_{B^0} - m_{B^+})$, and m_{B^0} to determine m_{B^+}, m_{B^0}, and the mass difference.

VALUE (MeV)	EVTS	DOCUMENT ID		TECN	COMMENT

5278.6 ± 0.8 ± 2.0		BEBEK	87	CLEO	$e^+e^- \to \Upsilon(4S)$

[1] CSORNA 00 uses fully reconstructed 526 $B^+ \to J/\psi^{(\prime)}K^+$ events and invariant masses without beam constraint.
[2] ALBRECHT 90J assumes 10580 for $\Upsilon(4S)$ mass. Supersedes ALBRECHT 87C and ALBRECHT 87D.
[3] Found using fully reconstructed decays with $J/\psi(1S)$. ALBRECHT 87D assume $m_{\Upsilon(4S)}$ = 10577 MeV.

$B^{\pm}$ MEAN LIFE

See $B^{\pm}/B^0/B_s^0/b$-baryon ADMIXTURE section for data on B-hadron mean life averaged over species of bottom particles.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account corrections between the measurements and asymmetric lifetime errors.

[4] Events are selected in which one B meson is fully reconstructed while the second B meson is reconstructed inclusively.
[5] Measured mean life using fully reconstructed decays.
[6] Data analyzed using $D/D^*\ell$X event vertices.
[7] Data analyzed using charge of secondary vertex.
[8] ABREU 95Q assumes $B(B^0 \rightarrow D^{**-}\ell^+\nu_\ell) = 3.2 \pm 1.7\%$.
[9] Data analyzed using vertex-charge technique to tag B charge.
[10] Combined result of $D/D^*\ell$X analysis and fully reconstructed B analysis.
[11] Combined ABREU 95Q and ADAM 95 result.

B^+ DECAY MODES

B^- modes are charge conjugates of the modes below. Modes which do not identify the charge state of the B are listed in the $B^{\pm}/B^0$ ADMIXTURE section.

The branching fractions listed below assume 50% $B^0\overline{B}^0$ and 50% B^+B^- production at the $\Upsilon(4S)$. We have attempted to bring older measurements up to date by rescaling their assumed $\Upsilon(4S)$ production ratio to 50:50 and their assumed D, D_s, D^*, and ψ branching ratios to current values whenever this would affect our averages and best limits significantly.

Indentation is used to indicate a subchannel of a previous reaction. All resonant subchannels have been corrected for resonance branching fractions to the final state so the sum of the subchannel branching fractions can exceed that of the final state.

For inclusive branching fractions, *e.g.*, $B \rightarrow D^{\pm}$ anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

[a] An ℓ indicates an e or a μ mode, not a sum over these modes.

[b] An $CP(\pm 1)$ indicates the CP=+1 and CP=−1 eigenstates of the D^0-$\overline{D}^0$ system.

CONSTRAINED FIT INFORMATION

An overall fit to 3 branching ratios uses 9 measurements and one constraint to determine 3 parameters. The overall fit has a χ^2 = 1.1 for 7 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\rm total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

0.0194 ± 0.0015 ± 0.0034	[15] ATHANAS	97	CLE2	Repl. by BARTELT 99

[13] Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

[14] FULTON 91 assumes equal production of $B^0\overline{B}^0$ and B^+B^- at the $\Upsilon(4S)$.

[15] ATHANAS 97 uses missing energy and missing momentum to reconstruct neutrino.

$\Gamma(\overline{D}^*(2007)^0 \ell^+ \nu_\ell)/\Gamma_{\rm total}$ Γ_3/Γ

ℓ = e or μ, not sum over e and μ modes.

0.070 ± 0.018 ± 0.014		[22] ANTREASYAN	90B	CBAL	$e^+e^- \to \Upsilon(4S)$

[16] Simultaneous measurements of both $B^0 \to D^*(2010)^- \ell \nu$ and $B^+ \to \overline{D}(2007)^0 \ell \nu$.

[17] ALBRECHT 92C reports 0.058 ± 0.014 ± 0.013. We rescale using the method described in STONE 94 but with the updated PDG 94 B($D^0 \to K^-\pi^+$). Assumes equal production of $B^0\overline{B}^0$ and B^+B^- at the $\Upsilon(4S)$.

[18] The results are based on the same analysis and data sample reported in ADAM 03.

[19] BARISH 95 use B($D^0 \to K^-\pi^+$) = (3.91 ± 0.08 ± 0.17)% and B($D^{*0} \to D^0\pi^0$) = (63.6 ± 2.3 ± 3.3)%.

[20] Combining $\overline{D}^{*0}\ell^+\nu_\ell$ and $\overline{D}^{*-}\ell^+\nu_\ell$ SANGHERA 93 test $V-A$ structure and fit the decay angular distributions to obtain $A_{FB} = 3/4*(\Gamma^- - \Gamma^+)/\Gamma = 0.14 \pm 0.06 \pm 0.03$. Assuming a value of V_{cb}, they measure V, A_1, and A_2, the three form factors for the $D^*\ell\nu_\ell$ decay, where results are slightly dependent on model assumptions.

[21] Assumes equal production of $B^0\overline{B}^0$ and B^+B^- at the $\Upsilon(4S)$. Uncorrected for D and D^* branching ratio assumptions.

[22] ANTREASYAN 90B is average over B and $\overline{D}^*(2010)$ charge states.

$\Gamma(\overline{D}_1(2420)^0 \ell^+ \nu_\ell)/\Gamma_{\rm total}$ Γ_4/Γ

[383] Assumes equal production of B^0 and B^+ at $\Upsilon(4S)$. The second error is a total of systematic uncertainties including model dependence.
[384] Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.
[385] The result is for di-lepton masses above 0.5 GeV.
[386] AFFOLDER 99B measured relative to $B^+\to J/\psi(1S)K^+$.
[387] ABE 96L measured relative to $B^+\to J/\psi(1S)K^+$ using PDG 94 branching ratios.
[388] ALBRECHT 91E reports $<2.2\times10^{-4}$ assuming the $\Upsilon(4S)$ decays 45% to $B^0\overline{B}^0$. We rescale to 50%.
[389] WEIR 90B assumes B^+ production cross section from LUND.
[390] AVERY 89B reports $<1.5\times10^{-4}$ assuming the $\Upsilon(4S)$ decays 43% to $B^0\overline{B}^0$. We rescale to 50%.
[391] AVERY 87 reports $<3.2\times10^{-4}$ assuming the $\Upsilon(4S)$ decays 40% to $B^0\overline{B}^0$. We rescale to 50%.

B^0

$I(J^P) = \frac{1}{2}(0^-)$

Quantum numbers not measured. Values shown are quark-model predictions.

See also the $B^{\pm}/B^0$ ADMIXTURE and $B^{\pm}/B^0/B_s^0$/b-baryon ADMIXTURE sections.

See the Note "Production and Decay of b-flavored Hadrons" at the beginning of the $B^{\pm}$ Particle Listings and the Note on "B^0-$\overline{B}^0$ Mixing" near the end of the B^0 Particle Listings.

B^0 MASS

The fit uses $m_{B^{+}}$, $(m_{B^0} - m_{B^+})$, and m_{B^0} to determine m_{B^+}, m_{B^0}, and the mass difference.

VALUE (MeV)	EVTS	DOCUMENT ID		TECN	COMMENT

Meson Particle Listings

B^0

[1] CSORNA 00 uses fully reconstructed 135 $B^0 \to J/\psi^{(\prime)} K^0_S$ events and invariant masses without beam constraint.
[2] ALBRECHT 90J assumes 10580 for $\Upsilon(4S)$ mass. Supersedes ALBRECHT 87C and ALBRECHT 87D.
[3] Found using fully reconstructed decays with J/ψ. ALBRECHT 87D assume $m_{\Upsilon(4S)} =$ 10577 MeV.

$m_{B^0} - m_{B^+}$

2.0 ± 1.1 ± 0.3	[4]	BEBEK	87	CLEO	$e^+e^- \to \Upsilon(4S)$

[4] BEBEK 87 actually measure the difference between half of $E_{\rm cm}$ and the $B^\pm$ or B^0 mass, so the $m_{B^0} - m_{B^\pm}$ is more accurate. Assume $m_{\Upsilon(4S)} =$ 10580 MeV.

$m_{B^0_H} - m_{B^0_L}$

See the B^0-$\overline{B}^0$ MIXING PARAMETERS section near the end of these B^0 Listings.

B^0 MEAN LIFE

See $B^\pm/B^0/B^0_s/b$-baryon ADMIXTURE section for data on B-hadron mean life averaged over species of bottom particles.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account corrections between the measurements and asymmetric lifetime errors.

[5] AUBERT 03C uses a sample of approximately 14,000 exclusively reconstructed $B^0 \to D^*(2010)^- \ell\nu$ and simultaneously measures the lifetime and oscillation frequency.
[6] Measurement performed with decays $B^0 \to D^{*-}\pi^+$ and $B^0 \to D^{*-}\rho^+$ using a partial reconstruction technique.
[7] Events are selected in which one B meson is fully reconstructed while the second B meson is reconstructed inclusively.
[8] Measured mean life using fully reconstructed decays.
[9] Data analyzed using partially reconstructed $\overline{B}^0 \to D^{*+}\ell^-\overline{\nu}$ decays.
[10] Data analyzed using $D/D^*\ell$X event vertices.
[11] Data analyzed using charge of secondary vertex.
[12] Data analyzed using inclusive $D/D^*\ell X$.
[13] Measured mean life using partially reconstructed $D^{*-}\pi^+$X vertices.
[14] ABREU 95Q assumes B($B^0 \to D^{**-}\ell^+\nu_\ell$) = 3.2 ± 1.7%.
[15] Data analyzed using vertex-charge technique to tag B charge.
[16] AKERS 95T assumes B($B^0 \to D_s^{(*)}D^{0(*)}$) = 5.0 ± 0.9% to find B^+/B^0 yield.
[17] Combined result of $D/D^*\ell$x analysis, fully reconstructed B analysis, and partially reconstructed $D^{*-}\pi^+$X analysis.
[18] Combined ABREU 95Q and ADAM 95 result.
[19] WAGNER 90 tagged B^0 mesons by their decays into $D^{*-}e^+\nu$ and $D^{*-}\mu^+\nu$ where the D^{*-} is tagged by its decay into $\pi^-\overline{D}^0$.
[20] AVERILL 89 is an estimate of the B^0 mean lifetime assuming that $B^0 \to D^{*+}$ + X always.

MEAN LIFE RATIO τ_{B^+}/τ_{B^0}

τ_{B^+}/τ_{B^0} (direct measurements)

[21] Events are selected in which one B meson is fully reconstructed while the second B meson is reconstructed inclusively.
[22] Measured using fully reconstructed decays.
[23] Data analyzed using $D/D^*\ell$X vertices.
[24] Data analyzed using charge of secondary vertex.
[25] ABREU 95Q assumes B($B^0 \to D^{**-}\ell^+\nu_\ell$) = 3.2 ± 1.7%.
[26] Data analyzed using vertex-charge technique to tag B charge.
[27] AKERS 95T assumes B($B^0 \to D_s^{(*)}D^{0(*)}$) = 5.0 ± 0.9% to find B^+/B^0 yield.
[28] Combined result of $D/D^*\ell$X analysis and fully reconstructed B analysis.

τ_{B^+}/τ_{B^0} (inferred from branching fractions)

These measurements are inferred from the branching fractions for semileptonic decay or other spectator-dominated decays by assuming that the rates for such decays are equal for B^0 and B^+. We do not use measurements which assume equal production of B^0 and B^+ because of the large uncertainty in the production ratio.

0.49 to 2.3	90		[34] BEAN	87B	CLEO	$e^+e^- \to \Upsilon(4S)$

[29] ARTUSO 97 uses partial reconstruction of $B \to D^* \ell \nu_\ell$ and independent of B^0 and B^+ production fraction.
[30] Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.
[31] ATHANAS 94 uses events tagged by fully reconstructed B^- decays and partially or fully reconstructed B^0 decays.
[32] Assumes equal production of B^0 and B^+.
[33] ALBRECHT 92G data analyzed using $B \to D_s \overline{D}$, $D_s \overline{D}^*$, $D_s^* \overline{D}$, $D_s^* \overline{D}^*$ events.
[34] BEAN 87B assume the fraction of $B^0 \overline{B}^0$ events at the $\Upsilon(4S)$ is 0.41.

$|\Delta\Gamma_{B^0_d}|/\Gamma_{B^0_d}$

$\Gamma_{B^0_d}$ and $|\Delta\Gamma_{B^0_d}|$ are the decay rate average and difference between two B^0_d CP eigenstates.

[35] Using the measured $\tau_{B^0} = 1.55 \pm 0.03$ ps.
[36] BEHRENS 00B uses high-momentum lepton tags and partially reconstructed $\overline{B}^0 \to D^{*+}\pi^-$, ρ^- decays to determine the flavor of the B meson.
[37] Assumes $\Delta_{md} = 0.478 \pm 0.018\ \text{ps}^{-1}$ and $\tau_{B^0} = 1.548 \pm 0.032$ ps.

B^0 DECAY MODES

$\overline{B}^0$ modes are charge conjugates of the modes below. Reactions indicate the weak decay vertex and do not include mixing. Modes which do not identify the charge state of the B are listed in the $B^\pm/B^0$ ADMIXTURE section.

The branching fractions listed below assume 50% $B^0\overline{B}^0$ and 50% B^+B^- production at the $\Upsilon(4S)$. We have attempted to bring older measurements up to date by rescaling their assumed $\Upsilon(4S)$ production ratio to 50:50 and their assumed D, D_S, D^*, and ψ branching ratios to current values whenever this would affect our averages and best limits significantly.

Indentation is used to indicate a subchannel of a previous reaction. All resonant subchannels have been corrected for resonance branching fractions to the final state so the sum of the subchannel branching fractions can exceed that of the final state.

For inclusive branching fractions, *e.g.*, $B \to D^\pm$ anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

[a] An ℓ indicates an e or a μ mode, not a sum over these modes.

[b] B^0 and B^0_s contributions not separated. Limit is on weighted average of the two decay rates.

[c] The value is for the sum of the charge states or particle/antiparticle states indicated.

B^0 BRANCHING RATIOS

For branching ratios in which the charge of the decaying B is not determined, see the $B^\pm$ section.

$\Gamma(\ell^+\nu_\ell \text{anything})/\Gamma_{\text{total}}$ Γ_1/Γ

$0.109\ \pm0.007\ \pm0.011$	ATHANAS	94	CLE2	Sup. by ARTUSO 97

[38] ARTUSO 97 uses partial reconstruction of $B \to D^*\ell\nu_\ell$ and inclusive semileptonic branching ratio from BARISH 96B ($0.1049 \pm 0.0017 \pm 0.0043$).

$\Gamma(D^-\ell^+\nu_\ell)/\Gamma_{\text{total}}$ Γ_2/Γ

ℓ denotes e or μ, not the sum.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account corrections between the measurements.

$0.020\ \pm0.007\ \pm0.006$	[43] ALBRECHT	89J	ARG	$e^+e^- \to \Upsilon(4S)$

[39] Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

[40] BUSKULIC 97 assumes fraction (B^+) = fraction (B^0) = (37.8 ± 2.2)% and PDG 96 values for B lifetime and branching ratio of D^* and D decays.

[41] ATHANAS 97 uses missing energy and missing momentum to reconstruct neutrino.

[42] FULTON 91 assumes assuming equal production of B^0 and B^+ at the $\Upsilon(4S)$ and uses Mark III D and D^* branching ratios.

[43] ALBRECHT 89J reports $0.018 \pm 0.006 \pm 0.005$. We rescale using the method described in STONE 94 but with the updated PDG 94 B($D^0 \to K^-\pi^+$).

$\Gamma(D^*(2010)^-\ell^+\nu_\ell)/\Gamma_{\text{total}}$ Γ_3/Γ

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account corrections between the measurements.

$0.070\ \pm0.012\ \pm0.019$	47	[61] ALBRECHT	87J	ARG	$e^+e^- \to \Upsilon(4S)$

[44] Uses the combined fit of both $B^0 \to D^*(2010)^-\ell\nu$ and $B^+ \to \overline{D}(2007)^0\ell\nu$ samples.

[45] Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

[46] ABREU 01H measured using about 5000 partial reconstructed D^* sample.

[47] ABBIENDI 00Q assumes the fraction B($b \to B^0$)= $(39.7^{+1.8}_{-2.2})$%. This result is an average of two methods using exclusive and partial D^* reconstruction.

[48] BUSKULIC 97 assumes fraction (B^+) = fraction (B^0) = (37.8 ± 2.2)% and PDG 96 values for B lifetime and D^* and D branching fractions.

[49] The results are based on the same analysis and data sample reported in ADAM 03.

[50] ACKERSTAFF 97G assumes fraction (B^+) = fraction (B^0) = (37.8 ± 2.2)% and PDG 96 values for B lifetime and branching ratio of D^* and D decays.

[51] ABREU 96P result is the average of two methods using exclusive and partial D^* reconstruction.

[52] BARISH 95 use B($D^0 \to K^-\pi^+$) = $(3.91 \pm 0.08 \pm 0.17)$% and B($D^{*+} \to D^0\pi^+$) = $(68.1 \pm 1.0 \pm 1.3)$%.

[53] BUSKULIC 95N assumes fraction (B^+) = fraction (B^0) = $38.2 \pm 1.3 \pm 2.2$% and τ_{B^0} = 1.58 ± 0.06 ps. $\Gamma(D^{*-}\ell^+\nu_\ell)$/total = [5.18 − 0.13(fraction(B^0)− 38.2)− 1.5(τ_{B^0} − 1.58)]%.

[54] ALBRECHT 94 assumes B($D^{*+} \to D^0\pi^+$) = $68.1 \pm 1.0 \pm 1.3$%. Uses partial reconstruction of D^{*+} and is independent of D^0 branching ratios.

[55] ALBRECHT 93 reports $0.052 \pm 0.005 \pm 0.006$. We rescale using the method described in STONE 94 but with the updated PDG 94 B($D^0 \to K^-\pi^+$). We have taken their average e and μ value. They also obtain α= $2*\Gamma^0/(\Gamma^- + \Gamma^+) - 1 = 1.1 \pm 0.4 \pm 0.2$, $A_{AF} = 3/4*(\Gamma^- - \Gamma^+)/\Gamma = 0.2 \pm 0.08 \pm 0.06$ and a value of $|V_{cb}| = 0.036$–0.045 depending on model assumptions.

[56] Combining $\overline{D}^{*0}\ell^+\nu_\ell$ and $\overline{D}^{*-}\ell^+\nu_\ell$ SANGHERA 93 test $V-A$ structure and fit the decay angular distributions to obtain $A_{FB} = 3/4*(\Gamma^- - \Gamma^+)/\Gamma = 0.14 \pm 0.06 \pm 0.03$. Assuming a value of V_{cb}, they measure V, A_1, and A_2, the three form factors for the $D^*\ell\nu_\ell$ decay, where results are slightly dependent on model assumptions.

[57] ANTREASYAN 90B is average over B and $\overline{D}^*(2010)$ charge states.

[58] The measurement of ALBRECHT 89C suggests a D^* polarization γ_L/γ_T of 0.85 ± 0.45. or $\alpha = 0.7 \pm 0.9$.

[59] ALBRECHT 89J is ALBRECHT 87J value rescaled using B($D^*(2010)^- \to D^0\pi^-$) = $0.57 \pm 0.04 \pm 0.04$. Superseded by ALBRECHT 93.

[60] We have taken average of the BORTOLETTO 89B values for electrons and muons, $0.046 \pm 0.005 \pm 0.007$. We rescale using the method described in STONE 94 but with the updated PDG 94 B($D^0 \to K^-\pi^+$). The measurement suggests a D^* polarization parameter value $\alpha = 0.65 \pm 0.66 \pm 0.25$.

[61] ALBRECHT 87J assume μ-e universality, the B($\Upsilon(4S) \to B^0\overline{B}^0$) = 0.45, the B($D^0 \to K^-\pi^+$) = $(0.042 \pm 0.004 \pm 0.004)$, and the B($D^*(2010)^- \to D^0\pi^-$) = 0.49 ± 0.08. Superseded by ALBRECHT 89J.

• • • We do not use the following data for averages, fits, limits, etc. • • •					
$2.69 \pm 0.41 \,^{+0.61}_{-0.64}$		[65] BEHRENS	00	CLE2	$e^+e^- \to \Upsilon(4S)$
$2.5 \pm 0.4 \,^{+0.7}_{-0.9}$		[66] ALEXANDER	96T	CLE2	Repl. by BEHRENS 00
<4.1	90	[67] BEAN	93B	CLE2	$e^+e^- \to \Upsilon(4S)$

[62] ATHAR 03 reports systematic errors $^{+0.47}_{-0.5} \pm 0.41 \pm 0.01$, which are experimental systematic, systematic due to residual form-factor uncertainties in the signal, and systematic due to residual form-factor uncertainties in the cross-feed modes, respectively. We combine these in quadrature.

[63] Uses isospin constraints and extrapolation to all electron energies according to five different form-factor calculations. The second error combines the systematic and theoretical uncertainties in quadrature.

[64] Averaging with ALEXANDER 96T results including experimental and theoretical correlations considered, BEHRENS 00 reports systematic errors $^{+0.33}_{-0.46} \pm 0.41$, where the second error is theoretical model dependence. We combine these in quadrature.

[65] BEHRENS 00 reports $^{+0.35}_{-0.40} \pm 0.50$, where the second error is the theoretical model dependence. We combine these in quadrature. B^+ and B^0 decays combined using isospin symmetry: $\Gamma(B^0 \to \rho^- \ell^+ \nu) = 2\Gamma(B^+ \to \rho^0 \ell^+ \nu) \approx 2\Gamma(B^+ \to \omega \ell^+ \nu)$. No evidence for $\omega \ell \nu$ is reported.

[66] ALEXANDER 96T reports $^{+0.5}_{-0.7} \pm 0.5$ where the second error is the theoretical model dependence. We combine these in quadrature. B^+ and B^0 decays combined using isospin symmetry: $\Gamma(B^0 \to \rho^- \ell^+ \nu) = 2\Gamma(B^+ \to \rho^0 \ell^+ \nu) \approx 2\Gamma(B^+ \to \omega \ell^+ \nu)$. No evidence for $\omega \ell \nu$ is reported.

[67] BEAN 93B limit set using ISGW Model. Using isospin and the quark model to combine $\Gamma(\rho^0 \ell^+ \nu_\ell)$ and $\Gamma(\omega \ell^+ \nu_\ell)$ with this result, they obtain a limit $< (1.6\text{–}2.7) \times 10^{-4}$ at 90% CL for $B^+ \to (\omega \text{ or } \rho^0) \ell^+ \nu_\ell$. The range corresponds to the ISGW, WSB, and KS models. An upper limit on $|V_{ub}/V_{cb}| < 0.08\text{–}0.13$ at 90% CL is derived as well.

700 ±500		5	[89] BEHRENDS	83	CLEO	$e^+e^- \to \Upsilon(4S)$

[85] Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

[86] No assumption about the intermediate mechanism is made in the analysis.

[87] BORTOLETTO 92 assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$ and uses Mark III branching fractions for the D. The product branching fraction into $D_0^*(2340)\pi$ followed by $D_0^*(2340) \to D^0\pi$ is < 0.0001 at 90% CL and into $D_2^*(2460)$ followed by $D_2^*(2460) \to D^0\pi$ is < 0.0004 at 90% CL.

[88] BEBEK 87 assume the $\Upsilon(4S)$ decays 43% to $B^0\overline{B}^0$. We rescale to 50%. $\mathrm{B}(D^0 \to K^-\pi^+) = (4.2 \pm 0.4 \pm 0.4)\%$ and $\mathrm{B}(D^0 \to K^-\pi^+\pi^+\pi^-) = (9.1 \pm 0.8 \pm 0.8)\%$ were used.

[89] Corrected by us using assumptions: $\mathrm{B}(D^0 \to K^-\pi^+) = (0.042 \pm 0.006)$ and $\mathrm{B}(\Upsilon(4S) \to B^0\overline{B}^0) = 50\%$. The product branching ratio is $\mathrm{B}(B^0 \to \overline{D}^0\pi^+\pi^-)\mathrm{B}(\overline{D}^0 \to K^+\pi^-) = (0.39 \pm 0.26) \times 10^{-2}$.

[90] BRANDENBURG 98 assume equal production of B^+ and B^0 at $\Upsilon(4S)$ and use the D^* reconstruction technique. The first error is their experiment's error and the second error is the systematic error from the PDG 96 value of $B(D^* \to D\pi)$.

[91] ALAM 94 assume equal production of B^+ and B^0 at the $\Upsilon(4S)$ and use the CLEO II $B(D^*(2010)^+ \to D^0\pi^+)$ and absolute $B(D^0 \to K^-\pi^+)$ and the PDG 1992 $B(D^0 \to K^-\pi^+\pi^0)/B(D^0 \to K^-\pi^+)$ and $B(D^0 \to K^-\pi^+\pi^+\pi^-)/B(D^0 \to K^-\pi^+)$.

[92] BORTOLETTO 92 reports $0.0040 \pm 0.0010 \pm 0.0007$ for $B(D^*(2010)^+ \to D^0\pi^+) = 0.57 \pm 0.06$. We rescale to our best value $B(D^*(2010)^+ \to D^0\pi^+) = (67.7 \pm 0.5) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$ and uses Mark III branching fractions for the D.

[93] ALBRECHT 90J reports $0.0028 \pm 0.0009 \pm 0.0006$ for $B(D^*(2010)^+ \to D^0\pi^+) = 0.57 \pm 0.06$. We rescale to our best value $B(D^*(2010)^+ \to D^0\pi^+) = (67.7 \pm 0.5) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$ and uses Mark III branching fractions for the D.

[94] BEBEK 87 reports $0.0028^{+0.0015}_{-0.0012}{}^{+0.0010}_{-0.0006}$ for $B(D^*(2010)^+ \to D^0\pi^+) = 0.57 \pm 0.06$. We rescale to our best value $B(D^*(2010)^+ \to D^0\pi^+) = (67.7 \pm 0.5) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Updated in BERKELMAN 91 to use same assumptions as noted for BORTOLETTO 92 and ALBRECHT 90J.

[95] Assumes $B(Z \to b\overline{b}) = 0.217$ and 38% B_d production fraction.

[96] ALBRECHT 87C use PDG 86 branching ratios for D and $D^*(2010)$ and assume $B(\Upsilon(4S) \to B^+B^-) = 55\%$ and $B(\Upsilon(4S) \to B^0\overline{B}^0) = 45\%$. Superseded by ALBRECHT 90J.

[97] ALBRECHT 86F uses pseudomass that is independent of D^0 and D^+ branching ratios.

[98] Assumes $B(D^*(2010)^+ \to D^0\pi^+) = 0.60^{+0.08}_{-0.15}$. Assumes $B(\Upsilon(4S) \to B^0\overline{B}^0) = 0.40 \pm 0.02$ Does not depend on D branching ratios.

0.024 ± 0.014	3	[143] BORTOLETTO 90	CLEO	$e^+e^- \to \Upsilon(4S)$

[138] AUBERT 03I reports $0.0103 \pm 0.0014 \pm 0.0013$ for $B(D_s^+ \to \phi\pi^+) = 0.036$. We rescale to our best value $B(D_s^+ \to \phi\pi^+) = (3.6 \pm 0.9) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

[139] AHMED 00B reports $0.0110 \pm 0.0018 \pm 0.0011$ for $B(D_s^+ \to \phi\pi^+) = 0.036$. We rescale to our best value $B(D_s^+ \to \phi\pi^+) = (3.6 \pm 0.9) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

[140] ALBRECHT 92G reports $0.014 \pm 0.010 \pm 0.003$ for $B(D_s^+ \to \phi\pi^+) = 0.027$. We rescale to our best value $B(D_s^+ \to \phi\pi^+) = (3.6 \pm 0.9) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes PDG 1990 D^+ and $D^*(2010)^+$ branching ratios, e.g., $B(D^0 \to K^-\pi^+) = 3.71 \pm 0.25\%$, $B(D^+ \to K^-\pi^+\pi^+) = 7.1 \pm 1.0\%$, and $B(D^*(2010)^+ \to D^0\pi^+) = 55 \pm 4\%$.

[141] BORTOLETTO 92 reports $0.016 \pm 0.009 \pm 0.006$ for $B(D_s^+ \to \phi\pi^+) = 0.030 \pm 0.011$. We rescale to our best value $B(D_s^+ \to \phi\pi^+) = (3.6 \pm 0.9) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$ and uses Mark III branching fractions for the D and $D^*(2010)$.

[142] GIBAUT 96 reports $0.0093 \pm 0.0023 \pm 0.0016$ for $B(D_s^+ \to \phi\pi^+) = 0.035$. We rescale to our best value $B(D_s^+ \to \phi\pi^+) = (3.6 \pm 0.9) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

[143] BORTOLETTO 90 assume $B(D_s \to \phi\pi^+) = 2\%$. Superseded by BORTOLETTO 92.

4.1 ±0.18	5	[267] ALAM	86	CLEO	Repl. by BEBEK 87

[256] Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

[257] ABE 98O reports $[B(B^0 \to J/\psi(1S)K^*(892)^0)]/[B(B^+ \to J/\psi(1S)K^+)] = 1.76 \pm 0.14 \pm 0.15$. We multiply by our best value $B(B^+ \to J/\psi(1S)K^+) = (9.9 \pm 1.0) \times 10^{-4}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

[258] Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

[259] BORTOLETTO 92 reports $1.1 \pm 0.5 \pm 0.3$ for $B(J/\psi(1S) \to e^+e^-) = 0.069 \pm 0.009$. We rescale to our best value $B(J/\psi(1S) \to e^+e^-) = (5.93 \pm 0.10) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

[260] ALBRECHT 90J reports $1.1 \pm 0.5 \pm 0.2$ for $B(J/\psi(1S) \to e^+e^-) = 0.069 \pm 0.009$. We rescale to our best value $B(J/\psi(1S) \to e^+e^-) = (5.93 \pm 0.10) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

[261] BEBEK 87 reports $3.5 \pm 1.6 \pm 0.3$ for $B(J/\psi(1S) \to e^+e^-) = 0.069 \pm 0.009$. We rescale to our best value $B(J/\psi(1S) \to e^+e^-) = (5.93 \pm 0.10) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Updated in BORTOLETTO 92 to use the same assumptions.

[262] ABE 96H assumes that $B(B^+ \to J/\psi K^+) = (1.02 \pm 0.14) \times 10^{-3}$.

[263] The neutral and charged B events together are predominantly longitudinally polarized, $\Gamma_L/\Gamma = 0.080 \pm 0.08 \pm 0.05$. This can be compared with a prediction using HQET, 0.73 (KRAMER 92). This polarization indicates that the $B \to \psi K^*$ decay is dominated by the $CP = -1$ CP eigenstate. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

[264] ALBRECHT 94G measures the polarization in the vector-vector decay to be predominantly longitudinal, $\Gamma_T/\Gamma = 0.03 \pm 0.16 \pm 0.15$ making the neutral decay a CP eigenstate when the K^{*0} decays through $K_S^0\pi^0$.

[265] ALBAJAR 91E assumes B_d^0 production fraction of 36%.

[266] ALBRECHT 87D assume $B^+B^-/B^0\overline{B}^0$ ratio is 55/45. Superseded by ALBRECHT 90J.

[267] ALAM 86 assumes $B^\pm/B^0$ ratio is 60/40. The observation of the decay $B^+ \to J/\psi K^*(892)^+$ (HAAS 85) has been retracted in this paper.

B^0–$\overline{B}^0$ MIXING

Updated December 2003 by O. Schneider (Federal Institute of Technology, Lausanne).

There are two neutral B^0–$\overline{B}^0$ meson systems, B^0_d–$\overline{B}^0_d$ and B^0_s–$\overline{B}^0_s$ (generically denoted B^0_q–$\overline{B}^0_q$, $q = s, d$), which exhibit particle-antiparticle mixing [1]. This mixing phenomenon is described in Ref. 2. In the following, we adopt the notation introduced in Ref. 2, and assume CPT conservation throughout. In each system, the light (L) and heavy (H) mass eigenstates,

$$|B_{\rm L,H}\rangle = p|B^0_q\rangle \pm q|\overline{B}^0_q\rangle\,, \qquad (1)$$

have a mass difference $\Delta m_q = m_{\rm H} - m_{\rm L} > 0$, and a total decay width difference $\Delta\Gamma_q = \Gamma_{\rm H} - \Gamma_{\rm L}$. In the absence of CP violation in the mixing, $|q/p| = 1$, these differences are given by $\Delta m_q = 2|M_{12}|$ and $|\Delta\Gamma_q| = 2|\Gamma_{12}|$, where M_{12} and Γ_{12} are the off-diagonal elements of the mass and decay matrices [2]. The evolution of a pure $|B^0_q\rangle$ or $|\overline{B}^0_q\rangle$ state at $t = 0$ is given by

$$|B^0_q(t)\rangle = g_+(t)\,|B^0_q\rangle + \frac{q}{p}\,g_-(t)\,|\overline{B}^0_q\rangle\,, \qquad (2)$$

$$|\overline{B}^0_q(t)\rangle = g_+(t)\,|\overline{B}^0_q\rangle + \frac{p}{q}\,g_-(t)\,|B^0_q\rangle\,, \qquad (3)$$

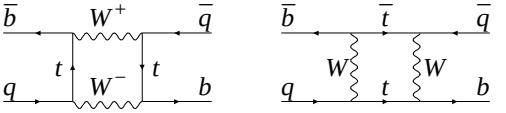

Figure 1: Dominant box diagrams for the $B^0_q \to \overline{B}^0_q$ transitions ($q = d$ or s). Similar diagrams exist where one or both t quarks are replaced with c or u quarks.

which means that the flavor states remain unchanged (+) or oscillate into each other (−) with time-dependent probabilities proportional to

$$|g_\pm(t)|^2 = \frac{e^{-\Gamma_q t}}{2}\left[\cosh\left(\frac{\Delta\Gamma_q}{2}t\right) \pm \cos(\Delta m_q\, t)\right]\,, \qquad (4)$$

where $\Gamma_q = (\Gamma_{\rm H} + \Gamma_{\rm L})/2$. In the absence of CP violation, the time-integrated mixing probability $\int |g_-(t)|^2\,dt/(\int |g_-(t)|^2\,dt + \int |g_+(t)|^2\,dt)$ is given by

$$\chi_q = \frac{x_q^2 + y_q^2}{2(x_q^2+1)}\,, \quad \text{where} \quad x_q = \frac{\Delta m_q}{\Gamma_q}\,, \quad y_q = \frac{\Delta\Gamma_q}{2\Gamma_q}\,. \qquad (5)$$

Standard Model predictions and phenomenology

In the Standard Model, the transitions $B^0_q \to \overline{B}^0_q$ and $\overline{B}^0_q \to B^0_q$ are due to the weak interaction. They are described, at the lowest order, by box diagrams involving two W bosons and two up-type quarks (see Fig. 1), as is the case for K^0–$\overline{K}^0$ mixing. However, the long range interactions arising from intermediate virtual states are negligible for the neutral B meson systems, because the large B mass is off the region of hadronic resonances. The calculation of the dispersive and absorptive parts of the box diagrams yields the following predictions for the off-diagonal element of the mass and decay matrices [3],

$$M_{12} = -\frac{G_F^2 m_W^2 \eta_B m_{B_q} B_{B_q} f_{B_q}^2}{12\pi^2}\, S_0(m_t^2/m_W^2)\,(V_{tq}^* V_{tb})^2\,, \qquad (6)$$

$$\Gamma_{12} = \frac{G_F^2 m_b^2 \eta'_B m_{B_q} B_{B_q} f_{B_q}^2}{8\pi} \times \left[(V_{tq}^* V_{tb})^2 + V_{tq}^* V_{tb} V_{cq}^* V_{cb}\; \mathcal{O}\left(\frac{m_c^2}{m_b^2}\right) + (V_{cq}^* V_{cb})^2\; \mathcal{O}\left(\frac{m_c^4}{m_b^4}\right)\right]\,, \qquad (7)$$

where G_F is the Fermi constant, m_W the W boson mass, and m_i the mass of quark i; m_{B_q}, f_{B_q} and B_{B_q} are the B^0_q mass, weak decay constant and bag parameter, respectively. The known function $S_0(x_t)$ can be approximated very well by $0.784\, x_t^{0.76}$ [4], and V_{ij} are the elements of the CKM matrix [5]. The QCD corrections η_B and η'_B are of order unity. The only non-negligible contributions to M_{12} are from box diagrams involving two top quarks. The phases of M_{12} and Γ_{12} satisfy

$$\phi_M - \phi_\Gamma = \pi + \mathcal{O}\left(\frac{m_c^2}{m_b^2}\right)\,, \qquad (8)$$

implying that the mass eigenstates have mass and width differences of opposite signs. This means that, like in the K^0–$\overline{K}^0$

system, the heavy state has a smaller decay width than that of the light state. Hence, $\Delta\Gamma$ is expected to be negative in the Standard Model.

Furthermore, the quantity

$$\left|\frac{\Gamma_{12}}{M_{12}}\right| \simeq \frac{3\pi}{2}\frac{m_b^2}{m_W^2}\frac{1}{S_0(m_t^2/m_W^2)} \sim \mathcal{O}\left(\frac{m_b^2}{m_t^2}\right) \qquad (9)$$

is small, and a power expansion of $|q/p|^2$ yields

$$\left|\frac{q}{p}\right|^2 = 1 + \left|\frac{\Gamma_{12}}{M_{12}}\right|\sin(\phi_M - \phi_\Gamma) + \mathcal{O}\left(\left|\frac{\Gamma_{12}}{M_{12}}\right|^2\right). \qquad (10)$$

Therefore, considering both Eqs. (8) and (9), the CP-violating parameter

$$1 - \left|\frac{q}{p}\right|^2 \simeq \mathrm{Im}\left(\frac{\Gamma_{12}}{M_{12}}\right) \qquad (11)$$

is expected to be very small: $\sim \mathcal{O}(10^{-3})$ for the B_d^0–$\overline{B}_d^0$ system and $\lesssim \mathcal{O}(10^{-4})$ for the B_s^0–$\overline{B}_s^0$ system [6].

In the approximation of negligible CP violation in mixing, the ratio $\Delta\Gamma_q/\Delta m_q$ is equal to the small quantity $|\Gamma_{12}/M_{12}|$ of Eq. (9); it is hence independent of CKM matrix elements, *i.e.*, the same for the B_d^0–$\overline{B}_d^0$ and B_s^0–$\overline{B}_s^0$ systems. It can be calculated with lattice QCD techniques; typical results are $\sim 5 \times 10^{-3}$ with quoted uncertainties of $\sim 30\%$. Given the current experimental knowledge (discussed below) on the mixing parameter x_q,

$$\begin{cases} x_d = 0.771 \pm 0.012 & (B_d^0\text{–}\overline{B}_d^0 \text{ system}) \\ x_s > 20.6 \text{ at } 95\% \text{ CL} & (B_s^0\text{–}\overline{B}_s^0 \text{ system}) \end{cases}, \qquad (12)$$

the Standard Model thus predicts that $\Delta\Gamma_d/\Gamma_d$ is very small (below 1%), but $\Delta\Gamma_s/\Gamma_s$ considerably larger ($\sim 10\%$). These width differences are caused by the existence of final states to which both the B_q^0 and $\overline{B}_q^0$ mesons can decay. Such decays involve $b \to c\overline{c}q$ quark-level transitions, which are Cabibbo-suppressed if $q = d$ and Cabibbo-allowed if $q = s$.

Experimental issues and methods for oscillation analyses

Time-integrated measurements of B^0–$\overline{B}^0$ mixing were published for the first time in 1987 by UA1 [7] and ARGUS [8], and since then by many other experiments. These measurements are typically based on counting same-sign and opposite-sign lepton pairs from the semileptonic decay of the produced $b\overline{b}$ pairs. Such analyses cannot easily separate the contributions from the different b-hadron species, therefore, the clean environment of $\Upsilon(4S)$ machines (where only B_d^0 and charged B_u mesons are produced) is in principle best suited to measure χ_d.

However, better sensitivity is obtained from time-dependent analyses aimed at the direct measurement of the oscillation frequencies Δm_d and Δm_s, from the proper time distributions of B_d^0 or B_s^0 candidates identified through their decay in (mostly) flavor-specific modes, and suitably tagged as mixed or unmixed. (This is particularly true for the B_s^0–$\overline{B}_s^0$ system, where the large value of x_s implies maximal mixing, *i.e.*, $\chi_s \simeq 1/2$.) In such analyses, the B_d^0 or B_s^0 mesons are either fully reconstructed, partially reconstructed from a charm meson, selected from a lepton with the characteristics of a $b \to \ell^-$ decay, or selected from a reconstructed displaced vertex. At high-energy colliders (LEP, SLC, Tevatron), the proper time $t = \frac{m_B}{p}L$ is measured from the distance L between the production vertex and the B decay vertex, and from an estimate of the B momentum p. At asymmetric B factories (KEKB, PEP-II), producing $e^+e^- \to \Upsilon(4S) \to B_d^0\overline{B}_d^0$ events with a boost $\beta\gamma$ (= 0.425, 0.55), the proper time difference between the two B candidates is estimated as $\Delta t \simeq \frac{\Delta z}{\beta\gamma c}$, where Δz is the spatial separation between the two B decay vertices along the boost direction. In all cases, the good resolution needed on the vertex positions is obtained with silicon detectors.

The average statistical significance $\mathcal{S}$ of a B_d^0 or B_s^0 oscillation signal can be approximated as [9]

$$\mathcal{S} \approx \sqrt{N/2}\, f_{\rm sig}\,(1-2\eta)\, e^{-(\Delta m\,\sigma_t)^2/2}, \qquad (13)$$

where N and $f_{\rm sig}$ are the number of candidates and the fraction of signal in the selected sample, η is the total mistag probability, and σ_t is the resolution on proper time (or proper time difference). The quantity $\mathcal{S}$ decreases very quickly as Δm increases; this dependence is controlled by σ_t, which is therefore a critical parameter for Δm_s analyses. At high-energy colliders, the proper time resolution $\sigma_t \sim \frac{m_B}{\langle p\rangle}\sigma_L \oplus t\frac{\sigma_p}{p}$ includes a constant contribution due to the decay length resolution σ_L (typically 0.05–0.3 ps), and a term due to the relative momentum resolution σ_p/p (typically 10–20% for partially reconstructed decays), which increases with proper time. At B factories, the boost of the B mesons is estimated from the known beam energies, and the term due to the spatial resolution dominates (typically 1–1.5 ps because of the much smaller B boost).

In order to tag a B candidate as mixed or unmixed, it is necessary to determine its flavor both in the initial state and in the final state. The initial and final state mistag probabilities, η_i and η_f, degrade $\mathcal{S}$ by a total factor $(1-2\eta) = (1-2\eta_i)(1-2\eta_f)$. In lepton-based analyses, the final state is tagged by the charge of the lepton from $b \to \ell^-$ decays; the biggest contribution to η_f is then due to $\overline{b} \to \overline{c} \to \ell^-$ decays. Alternatively, the charge of a reconstructed charm meson (D^{*-} from B_d^0 or D_s^- from B_s^0), or that of a kaon thought to come from a $b \to c \to s$ decay [10], can be used. For fully inclusive analyses based on topological vertexing, final state tagging techniques include jet charge [11] and charge dipole [12,13] methods.

At high-energy colliders, the methods to tag the initial state (*i.e.*, the state at production), can be divided in two groups: the ones that tag the initial charge of the $\overline{b}$ quark contained in the B candidate itself (same-side tag), and the ones that tag the initial charge of the other b quark produced in the event (opposite-side tag). On the same side, the charge of a track from the primary vertex is correlated with the production state of the B if that track is a decay product of a B^{**} state or the first particle in the fragmentation chain [14,15]. Jet- and vertex-charge techniques work on both sides and on the opposite side, respectively. Finally, the charge of a lepton from $b \to \ell^-$

or of a kaon from $b \to c \to s$ can be used as opposite side tags, keeping in mind that their performance is degraded due to integrated mixing. At SLC, the beam polarization produced a sizeable forward-backward asymmetry in the $Z \to b\overline{b}$ decays, and provided another very interesting and effective initial state tag based on the polar angle of the B candidate [12]. Initial state tags have also been combined to reach $\eta_i \sim 26\%$ at LEP [15,16], or even 22% at SLD [12] with full efficiency. In the case $\eta_f = 0$, this corresponds to an effective tagging efficiency (defined as $Q = \epsilon(1-2\eta)^2$, where ϵ is the tagging efficiency) in the range $23-31\%$. The equivalent figure at CDF is $\sim 3.5\%$ for Tevatron Run I [17] (expected to reach $\sim 5\%$ for Run II [18]), reflecting the fact that tagging is very challenging at hadron colliders.

At B factories, the flavor of a B^0_d meson at production cannot be determined, since the two neutral B mesons produced in a $\Upsilon(4S)$ decay evolve in a coherent P-wave state where they keep opposite flavors at any time. However, as soon as one of them decays, the other follows a time-evolution given by Eqs. (2) or (3), where t is replaced with Δt (which will take negative values half of the time). Hence, the "initial state" tag of a B can be taken as the final state tag of the other B. Effective tagging efficiencies $Q = 28-29\%$ are achieved by BABAR and Belle [19], using different techniques including $b \to \ell^-$ and $b \to c \to s$ tags. It is interesting to note that, in this case, mixing of this other B (*i.e.*, the coherent mixing occurring before the first B decay) does not contribute to the mistag probability.

In the absence of experimental evidence for a decay-width difference, oscillation analyses typically neglect $\Delta\Gamma$ in Eq. (4), and describe the data with the physics functions $\Gamma e^{-\Gamma t}(1 \pm \cos(\Delta m t))/2$ (high-energy colliders) or $\Gamma e^{-\Gamma|\Delta t|}(1 \pm \cos(\Delta m \Delta t))/4$ (asymmetric $\Upsilon(4S)$ machines). As can be seen from Eq. (4), a non-zero value of $\Delta\Gamma$ would effectively reduce the oscillation amplitude with a small time-dependent factor that would be very difficult to distinguish from time resolution effects. Measurements of Δm_d are usually extracted from the data using a maximum likelihood fit. No significant B^0_s–$\overline{B}^0_s$ oscillations have been seen so far. To extract information useful to set lower limits on Δm_s, B^0_s analyses follow a method [9] in which a B^0_s oscillation amplitude $\mathcal{A}$ is measured as a function of a fixed test value of Δm_s, using a maximum likelihood fit based on the functions $\Gamma_s e^{-\Gamma_s t}(1 \pm \mathcal{A}\cos(\Delta m_s t))/2$. To a very good approximation, the statistical uncertainty on $\mathcal{A}$ is Gaussian and equal to $1/\mathcal{S}$ from Eq. (13). If $\Delta m_s = \Delta m_s^{\rm true}$, one expects $\mathcal{A} = 1$ within the total uncertainty $\sigma_{\mathcal{A}}$; however, if Δm_s is (far) below its true value, a measurement consistent with $\mathcal{A} = 0$ is expected. A value of Δm_s can be excluded at 95% CL if $\mathcal{A} + 1.645\,\sigma_{\mathcal{A}} \leq 1$. If $\Delta m_s^{\rm true}$ is very large, one expects $\mathcal{A} = 0$, and all values of Δm_s such that $1.645\,\sigma_{\mathcal{A}}(\Delta m_s) < 1$ are expected to be excluded at 95% CL. Because of the proper time resolution, the quantity $\sigma_{\mathcal{A}}(\Delta m_s)$ is an increasing function of Δm_s, and one therefore expects to be able to exclude individual Δm_s values up to $\Delta m_s^{\rm sens}$, where $\Delta m_s^{\rm sens}$, called here the sensitivity of the analysis, is defined by $1.645\,\sigma_{\mathcal{A}}(\Delta m_s^{\rm sens}) = 1$.

B^0_d mixing studies

Many B^0_d–$\overline{B}^0_d$ oscillations analyses have been published by the ALEPH [20], BABAR [21], Belle [22], CDF [14], DELPHI [13,23], L3 [24], and OPAL [25] collaborations. Although a variety of different techniques have been used, the individual Δm_d results obtained at high-energy colliders have remarkably similar precision. Their average is compatible with the recent and more precise measurements from asymmetric B factories. The systematic uncertainties are not negligible; they are often dominated by sample composition, mistag probability, or b-hadron lifetime contributions. Before being combined, the measurements are adjusted on the basis of a common set of input values, including the b-hadron lifetimes and fractions published in this *Review*. Some measurements are statistically correlated. Systematic correlations arise both from common physics sources (fragmentation fractions, lifetimes, branching ratios of b hadrons), and from purely experimental or algorithmic effects (efficiency, resolution, tagging, background description). Combining all published measurements [13,14,20–25] and accounting for all identified correlations as described in Ref. 26, yields $\Delta m_d = 0.502 \pm 0.004(\text{stat}) \pm 0.005(\text{syst})$ ps^{-1}.

On the other hand, ARGUS and CLEO have published time-integrated measurements [27–29], which average to $\chi_d = 0.182 \pm 0.015$. Following Ref. 29, the width difference $\Delta\Gamma_d$ could in principle be extracted from the measured value of Γ_d and the above averages for Δm_d and χ_d (see Eq. (5)), provided that $\Delta\Gamma_d$ has a negligible impact on the Δm_d measurements. However, direct time-dependent studies yield stronger constraints: DELPHI published the result $|\Delta\Gamma_d|/\Gamma_d < 18\%$ at 95% CL [13], while BABAR recently obtained $-8.4\% < \text{sign}(\text{Re}\lambda_{\rm CP})\Delta\Gamma_{\rm d}/\Gamma_{\rm d} < 6.8\%$ at 90% CL [30].

Assuming $\Delta\Gamma_d = 0$ and no CP violation in mixing, and using the measured B^0_d lifetime, the Δm_d and χ_d results are combined to yield the world average

$$\Delta m_d = 0.502 \pm 0.007 \text{ ps}^{-1} \tag{14}$$

or, equivalently,

$$\chi_d = 0.186 \pm 0.004\,. \tag{15}$$

Evidence for CP violation in B^0_d mixing has been searched for, both with flavor-specific and inclusive B^0_d decays, in samples where the initial flavor state is tagged. In the case of semileptonic (or other flavor-specific) decays, where the final state tag is also available, the following asymmetry [2]

$$\mathcal{A}_{\rm SL} = \frac{N(\overline{B}^0_d(t) \to \ell^+\nu_\ell X) - N(B^0_d(t) \to \ell^-\overline{\nu}_\ell X)}{N(\overline{B}^0_d(t) \to \ell^+\nu_\ell X) + N(B^0_d(t) \to \ell^-\overline{\nu}_\ell X)} \simeq 1 - |q/p|^2_d \tag{16}$$

has been measured, either in time-integrated analyses at CLEO [28,29,31] and CDF [32], or in time-dependent analyses at LEP [33–35] and BABAR [30,36]. In the inclusive case,

also investigated at LEP [34,35,37], no final state tag is used, and the asymmetry [38]

$$\frac{N(B^0_d(t) \to \text{all}) - N(\overline{B}^0_d(t) \to \text{all})}{N(B^0_d(t) \to \text{all}) + N(\overline{B}^0_d(t) \to \text{all})} \simeq \mathcal{A}_{\rm SL}\left[\frac{x_d}{2}\sin(\Delta m_d\, t) - \sin^2\left(\frac{\Delta m_d\, t}{2}\right)\right] \quad (17)$$

must be measured as a function of the proper time to extract information on CP violation. In all cases, asymmetries compatible with zero have been found, with a precision limited by the available statistics. A simple average of all published results for the B^0_d meson [29,31,33,35–37] yields $\mathcal{A}_{\rm SL} = +0.002 \pm 0.013$, or $|q/p|_d = 0.999 \pm 0.006$, a result which does not yet constrain the Standard Model.

The Δm_d result of Eq. (14) provides an estimate of $2|M_{12}|$, and can be used, together with Eq. (6), to extract the magnitude of the CKM matrix element V_{td} within the Standard Model [39]. The main experimental uncertainties on the resulting estimate of $|V_{td}|$ come from m_t and Δm_d; however, the extraction is at present completely dominated by the uncertainty on the hadronic matrix element $f_{B_d}\sqrt{B_{B_d}} = 221 \pm 28^{+0}_{-22}$ MeV obtained from lattice QCD calculations [40].

B^0_s mixing studies

B^0_s–$\overline{B}^0_s$ oscillations have been the subject of many studies from ALEPH [15,41], CDF [42], DELPHI [13,16,43,44], OPAL [45], and SLD [12,46,47]. No oscillation signal has been found so far. The most sensitive analyses appear to be the ones based on inclusive lepton samples at LEP. Because of their better proper time resolution, the small data samples analyzed inclusively at SLD, as well as the few fully reconstructed B_s decays at LEP, turn out to be also very useful to explore the high Δm_s region.

All results are limited by the available statistics. They can easily be combined, since all experiments provide measurements of the B^0_s oscillation amplitude. All published results [12,13,16,41,42,43,45,46] are averaged using the procedure of Ref. 26 to yield the combined amplitudes $\mathcal{A}$ shown in Fig. 2 as a function of Δm_s. The individual results have been adjusted to common physics inputs, and all known correlations have been accounted for; the sensitivities of the inclusive analyses, which depend directly through Eq. (13) on the assumed fraction f_s of B^0_s mesons in an unbiased sample of weakly-decaying b hadrons, have also been rescaled to a common average of $f_s = 0.107 \pm 0.011$. The combined sensitivity for 95% CL exclusion of Δm_s values is found to be 17.8 ps^{-1}. All values of Δm_s below 14.4 ps^{-1} are excluded at 95% CL, which we express as

$$\Delta m_s > 14.4 \text{ ps}^{-1} \quad \text{at 95\% CL}. \quad (18)$$

The values between 14.4 and 21.8 ps^{-1} cannot be excluded, because the data is compatible with a signal in this region.

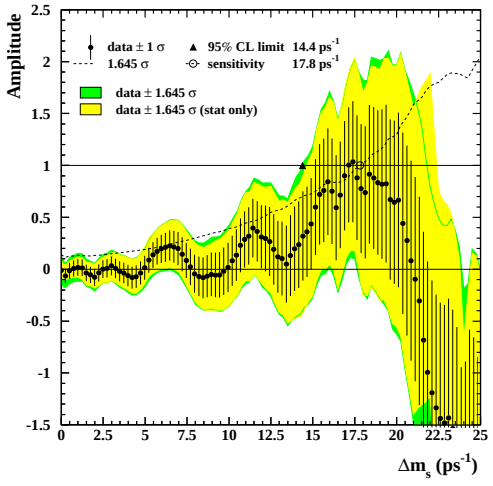

Figure 2: Combined measurements of the B^0_s oscillation amplitude as a function of Δm_s, including all results published by November 2003. The measurements are dominated by statistical uncertainties. Neighboring points are statistically correlated. See full-color version on color pages at end of book.

However, no deviation from $\mathcal{A} = 0$ is seen in Fig. 2 that would indicate the observation of a signal.

Some Δm_s analyses are still unpublished [44,47]. Including these in the above combination would yield $\Delta m_s > 14.6$ ps^{-1} at 95% CL with a sensitivity of 19.3 ps^{-1}.

The information on $|V_{ts}|$ obtained, in the framework of the Standard Model, from the combined amplitude spectrum, is hampered by the hadronic uncertainty, as in the B^0_d case. However, several uncertainties cancel in the frequency ratio

$$\frac{\Delta m_s}{\Delta m_d} = \frac{m_{B_s}}{m_{B_d}}\,\xi^2\left|\frac{V_{ts}}{V_{td}}\right|^2, \quad (19)$$

where $\xi = (f_{B_s}\sqrt{B_{B_s}})/(f_{B_d}\sqrt{B_{B_d}}) = 1.15 \pm 0.05^{+0.12}_{-0.00}$ is an SU(3) flavor-symmetry breaking factor obtained from lattice QCD calculations [40]. The CKM matrix can be constrained using the experimental results on Δm_d, Δm_s, $|V_{ub}/V_{cb}|$, ϵ_K, and $\sin(2\beta)$ together with theoretical inputs and unitarity conditions [39,48]. Given all measurements other than Δm_d and Δm_s, the constraint from our knowledge on the ratio $\Delta m_s/\Delta m_d$ is presently more effective in limiting the position of the apex of the CKM unitarity triangle than the one obtained from the Δm_d measurements alone, due to the reduced hadronic uncertainty in Eq. (19). We note also that it would be difficult for the Standard Model to accommodate values of Δm_s above ~ 25 ps^{-1} [48].

Information on $\Delta\Gamma_s$ can be obtained by studying the proper time distribution of untagged data samples enriched in B^0_s mesons [49]. In the case of an inclusive B^0_s selection [50], or a semileptonic B^0_s decay selection [16,51], both the short- and long-lived components are present, and the proper time distribution is a superposition of two exponentials with decay constants $\Gamma_s \pm \Delta\Gamma_s/2$. In principle, this provides sensitivity to

both Γ_s and $(\Delta\Gamma_s/\Gamma_s)^2$. Ignoring $\Delta\Gamma_s$ and fitting for a single exponential leads to an estimate of Γ_s with a relative bias proportional to $(\Delta\Gamma_s/\Gamma_s)^2$. An alternative approach, which is directly sensitive to first order in $\Delta\Gamma_s/\Gamma_s$, is to determine the lifetime of B_s^0 candidates decaying to CP eigenstates; measurements exist for $B_s^0 \to J/\psi\phi$ [52] and $B_s^0 \to D_s^{(*)+}D_s^{(*)-}$ [53], which are mostly CP-even states [54]. An estimate of $\Delta\Gamma_s/\Gamma_s$ has also been obtained directly from a measurement of the $B_s^0 \to D_s^{(*)+}D_s^{(*)-}$ branching ratio [53], under the assumption that these decays account for all the CP-even final states (however, no systematic uncertainty due to this assumption is given, so the average quoted below will not include this estimate).

Present data is not precise enough to efficiently constrain both Γ_s and $\Delta\Gamma_s/\Gamma_s$; since the B_s^0 and B_d^0 lifetimes are predicted to be equal within less than a percent [55], an expectation compatible with the current experimental data [56], the constraint $\Gamma_s = \Gamma_d$ can also be used to improve the extraction of $\Delta\Gamma_s/\Gamma_s$. Applying the combination procedure of Ref. 26 on the published results [16,51–53,57], yields

$$|\Delta\Gamma_s|/\Gamma_s < 0.54 \quad \text{at 95\% CL} \tag{20}$$

without external constraint, or

$$|\Delta\Gamma_s|/\Gamma_s < 0.29 \quad \text{at 95\% CL} \tag{21}$$

when constraining $1/\Gamma_s$ to the measured B_d^0 lifetime. These results are not yet precise enough to test Standard Model predictions.

Average b-hadron mixing and b-hadron production fractions at high energy

Let f_u, f_d, f_s and $f_{\rm baryon}$ be the fractions of B_u, B_d^0, B_s^0 and b-baryon composing an unbiased sample of weakly decaying b hadrons produced in high-energy colliders. LEP experiments have measured $f_s \times {\rm BR}(B_s^0 \to D_s^- \ell^+ \nu_\ell X)$ [58], ${\rm BR}(b \to \Lambda_b^0) \times {\rm BR}(\Lambda_b^0 \to \Lambda_c^+ \ell^- \overline{\nu}_\ell X)$ [59], and ${\rm BR}(b \to \Xi_b^-) \times {\rm BR}(\Xi_b^- \to \Xi^- \ell^- \overline{\nu}_\ell X)$ [60] from partially reconstructed final states, including a lepton, $f_{\rm baryon}$ from protons identified in b events [61], and the production rate of charged b hadrons [62]. The various b-hadron fractions have also been measured at CDF from electron-charm final states [63]. All these published results have been combined following the procedure and assumptions described in Ref. 26, to yield $f_u = f_d = (40.3 \pm 1.1)\%$, $f_s = (8.8 \pm 2.1)\%$, and $f_{\rm baryon} = (10.7 \pm 1.8)\%$ under the constraints

$$f_u = f_d \qquad \text{and} \qquad f_u + f_d + f_s + f_{\rm baryon} = 1\,. \tag{22}$$

Time-integrated mixing analyses performed with lepton pairs from $b\bar{b}$ events produced at high-energy colliders measure the quantity

$$\overline{\chi} = f'_d\,\chi_d + f'_s\,\chi_s\,, \tag{23}$$

where f'_d and f'_s are the fractions of B_d^0 and B_s^0 hadrons in a sample of semileptonic b-hadron decays. Assuming that all b hadrons have the same semileptonic decay width implies $f'_q = f_q/(\Gamma_q \tau_b)$ $(q = s, d)$, where τ_b is the average b-hadron lifetime. Hence $\overline{\chi}$ measurements can be used to improve our knowledge on the fractions f_u, f_d, f_s and $f_{\rm baryon}$.

Combining the above estimates of these fractions with the average $\overline{\chi} = 0.1257 \pm 0.0042$ (published in this *Review*), χ_d from Eq. (15), and $\chi_s = 1/2$ yields, under the constraints of Eq. (22),

$$f_u = f_d = (39.7 \pm 1.0)\%\,, \tag{24}$$

$$f_s = (10.7 \pm 1.1)\%\,, \tag{25}$$

$$f_{\rm baryon} = (9.9 \pm 1.7)\%\,, \tag{26}$$

showing that mixing information substantially reduces the uncertainty on f_s. These results and the averages quoted in Eqs. (14) and (15) for χ_d and Δm_d have been obtained in a consistent way by the B oscillations working group [26], taking into account the fact that many individual measurements of Δm_d depend on the assumed values for the b-hadron fractions.

Summary and prospects

B^0–$\overline{B}^0$ mixing has been and still is a field of intense study. The mass difference in the B_d^0–$\overline{B}_d^0$ system is very well measured (with an accuracy of 1.3%) but, despite an impressive theoretical effort, the hadronic uncertainty still limits the precision of the extracted estimate of $|V_{td}|$. The mass difference in the B_s^0–$\overline{B}_s^0$ system is much larger and still unmeasured. However, the current experimental lower limit on Δm_s already provides, together with Δm_d, a significant constraint on the CKM matrix within the Standard Model. No strong experimental evidence exists yet for the rather large decay width difference expected in the B_s^0–$\overline{B}_s^0$ system. It is interesting to recall that the ratio $\Delta\Gamma_s/\Delta m_s$ does not depend on CKM matrix elements in the Standard Model (see Eq. (9)), and that a measurement of either Δm_s or $\Delta\Gamma_s$ could be turned into a Standard Model prediction of the other one.

In the near future, the most promising prospects for B_s^0 mixing are from Run II at the Tevatron, where both Δm_s and $\Delta\Gamma_s$ are expected to be measured with fully reconstructed B_s^0 decays. The CDF and D0 collaborations expect to be able to observe B_s^0 oscillations with $2-3$ fb^{-1} of data, if Δm_s is consistent with the current Standard Model prediction [18]. Should this not be the case, then the discovery of B_s^0 oscillations will most likely be made at CERN's Large Hadron Collider scheduled to come into operation in 2007, where the LHC collaboration claims to have the potential to cover a Δm_s range up to ~ 68 ps^{-1} after 2 fb^{-1} of data (10^7 s) have been analyzed [64]. The BTeV experiment at Fermilab should have a comparable sensitivity to Δm_s and is expected to turn on in 2009 [65].

CP violation in B mixing, which has not been seen yet, as well as the phases involved in B mixing, will be further investigated with the large statistics that will become available at the B factories, the Tevatron, and the LHC.

B mixing may not have delivered all its secrets yet, because it is one of the phenomena where new physics might very well reveal itself (for example, new particles involved in the box

diagrams). Theoretical calculations in lattice QCD are becoming more reliable, and further progress in reducing hadronic uncertainties is expected. In the long term, a stringent check of the consistency, within the Standard Model, of the B^0_d and B^0_s mixing measurements, with all other measured observables in B physics (including CP asymmetries in B decays), will be possible, allowing to place limits on new physics or, better, discover new physics.

B^0-$\overline{B}^0$ MIXING PARAMETERS

For a discussion of B^0-$\overline{B}^0$ mixing see the note on "B^0-$\overline{B}^0$ Mixing" in the B^0 Particle Listings above.

χ_d is a measure of the time-integrated B^0-$\overline{B}^0$ mixing probability that a produced B^0 ($\overline{B}^0$) decays as a $\overline{B}^0$ (B^0). Mixing violates $\Delta B \neq 2$ rule.

$$\chi_d = \frac{x_d^2}{2(1+x_d^2)}$$

$$x_d = \frac{\Delta m_{B^0}}{\Gamma_{B^0}} = (m_{B^0_H} - m_{B^0_L})\,\tau_{B^0},$$

where H, L stand for heavy and light states of two B^0 CP eigenstates and $\tau_{B^0} = \frac{1}{0.5(\Gamma_{B^0_H}+\Gamma_{B^0_L})}$.

χ_d

This B^0-$\overline{B}^0$ mixing parameter is the probability (integrated over time) that a produced B^0 (or $\overline{B}^0$) decays as a $\overline{B}^0$ (or B^0), e.g. for inclusive lepton decays

$$\chi_d = \Gamma(B^0 \to \ell^- X \text{ (via } \overline{B}^0)) / \Gamma(B^0 \to \ell^{\pm} X)$$
$$= \Gamma(\overline{B}^0 \to \ell^+ X \text{ (via } B^0)) / \Gamma(\overline{B}^0 \to \ell^{\pm} X)$$

Where experiments have measured the parameter $r = \chi/(1-\chi)$, we have converted to χ. Mixing violates the $\Delta B \neq 2$ rule.

Note that the measurement of χ at energies higher than the $\Upsilon(4S)$ have not separated χ_d from χ_s where the subscripts indicate $B^0(\overline{b}d)$ or $B^0_s(\overline{b}s)$. They are listed in the $B^{\pm}/B^0/B^0_s/b$-baryon ADMIXTURE section.

The experiments at $\Upsilon(4S)$ make an assumption about the $B^0\overline{B}^0$ fraction and about the ratio of the $B^{\pm}$ and B^0 semileptonic branching ratios (usually that it equals one).

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account corrections between the measurements, includes χ_d calculated from Δm_{B^0} and τ_{B^0}.

[533] BEHRENS 00B uses high-momentum lepton tags and partially reconstructed $\overline{B}^0 \to D^{*+}\pi^-, \rho^-$ decays to determine the flavor of the B meson.
[534] ALBRECHT 94 reports r=0.194 ± 0.062 ± 0.054. We convert to χ for comparison. Uses tagged events (lepton + pion from D^*).
[535] BARTELT 93 analysis performed using tagged events (lepton+pion from D^*). Using dilepton events they obtain $0.157 \pm 0.016^{+0.033}_{-0.028}$.
[536] ALBRECHT 92L is a combined measurement employing several lepton-based techniques. It uses all previous ARGUS data in addition to new data and therefore supersedes ALBRECHT 87I. A value of $r = 20.6 \pm 7.0\%$ is directly measured. The value can be used to measure $x = \Delta M/\Gamma = 0.72 \pm 0.15$ for the B_d meson. Assumes $f_{+-}/f_0 = 1.0 \pm 0.05$ and uses $\tau_{B^{\pm}}/\tau_{B^0} = (0.95 \pm 0.14)$ (f_{+-}/f_0).
[537] Uses $D^{*+}K^{\pm}$ correlations.
[538] Uses $(D^{*+}\ell^-)\,K^{\pm}$ correlations.
[539] These experiments see a combination of B_s and B_d mesons.
[540] ALBRECHT 87I is inclusive measurement with like-sign dileptons, with tagged B decays plus leptons, and one fully reconstructed event. Measures r=0.21 ± 0.08. We convert to χ for comparison. Superseded by ALBRECHT 92L.
[541] BEAN 87B measured $r < 0.24$; we converted to χ.
[542] Same-sign dilepton events. Limit assumes semileptonic BR for B^+ and B^0 equal. If $B^0/B^{\pm}$ ratio <0.58, no limit exists. The limit was corrected in BEAN 87B from $r < 0.30$ to $r < 0.37$. We converted this limit to χ.

$\Delta m_{B^0} = m_{B^0_H} - m_{B^0_L}$

$\Delta m_{B^0_s}$ is a measure of 2π times the B^0-$\overline{B}^0$ oscillation frequency in time-dependent mixing experiments.

The second "OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account corrections between the measurements.

The first "OUR EVALUATION" (0.502 ± 0.007), also provided by the HFAG, includes Δm_d calculated from χ_d measured at $\Upsilon(4S)$.

[543] Events with a high transverse momentum lepton were removed and an inclusively reconstructed vertex was required.

[544] AUBERT 03C uses a sample of approximately 14,000 exclusively reconstructed $B^0 \to D^*(2010)^- \ell\nu$ and simultaneously measures the lifetime and oscillation frequency.

[545] HASTINGS 03 measurement based on the time evolution of dilepton events. It also reports $f_+/f_0 = 1.01 \pm 0.03 \pm 0.09$ and CPT violation parameters in B^0-$\overline{B}^0$ mixing.

[546] ZHENG 03 data analyzed using partially reconstructed $\overline{B}^0 \to D^{*-}\pi^+$ decay and a flavor tag based on the charge of the lepton from the accompanying B decay.

[547] Uses a tagged sample of fully-reconstructed neutral B decays at $\Upsilon(4S)$.

[548] Measured based on the time evolution of dilepton events in $\Upsilon(4S)$ decays.

[549] Uses a tagged sample of B^0 decays reconstructed in the mode $B^0 \to D^*\ell\nu$.

[550] Uses a tagged sample of fully-reconstructed hadronic B^0 decays at $\Upsilon(4S)$.

[551] Data analyzed using partially reconstructed $\overline{B}^0 \to D^{*+}\ell^-\overline{\nu}$ decay and a combination of flavor tags from the rest of the event.

[552] Uses di-muon events.

[553] Uses jet-charge and lepton-flavor tagging.

[554] Uses $\ell^- D^{*+} - \ell$ events.

[555] Uses π-B in the same side.

[556] Uses ℓ-ℓ.

[557] Uses ℓ-$Q_{\rm hem}$.

[558] Uses ℓ-ℓ with impact parameters.

[559] Uses $D^{*\pm}$-$Q_{\rm hem}$.

[560] Uses $\pi_s^\pm$ ℓ-$Q_{\rm hem}$.

[561] Uses $D^{*\pm}$-ℓ/$Q_{\rm hem}$.

[562] Uses $D^{*\pm}$ ℓ-$Q_{\rm hem}$.

[563] Uses $D^{*\pm}$-ℓ.

[564] AUBERT 02N result based on the same analysis and data sample reported in AUBERT 02I.

[565] ACCIARRI 98D combines results from ℓ-ℓ, ℓ-$Q_{\rm hem}$, and ℓ-ℓ with impact parameters.

[566] ABREU 97N combines results from $D^{*\pm}$-$Q_{\rm hem}$, ℓ-$Q_{\rm hem}$, $\pi_s^\pm$ ℓ-$Q_{\rm hem}$, and ℓ-ℓ.

[567] ACKERSTAFF 97V combines results from ℓ-ℓ, ℓ-$Q_{\rm hem}$, D^*-ℓ, and $D^{*\pm}$-$Q_{\rm hem}$.

[568] BUSKULIC 97D combines results from $D^{*\pm}$-ℓ/$Q_{\rm hem}$, ℓ-$Q_{\rm hem}$, and ℓ-ℓ.

[569] ABREU 96Q analysis performed using lepton, kaon, and jet-charge tags.

[570] ALEXANDER 96V combines results from $D^{*\pm}$-ℓ and $D^{*\pm}$ ℓ-$Q_{\rm hem}$.

[571] AKERS 95J combines results from charge measurement, $D^{*\pm}$ ℓ-$Q_{\rm hem}$ and ℓ-ℓ.

$x_d = \Delta m_{B^0}/\Gamma_{B^0}$

The second "OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account corrections between the measurements.

The first "OUR EVALUATION" (0.771 ± 0.012), also provided by the HFAG, includes χ_d measured at $\Upsilon(4S)$.

VALUE	DOCUMENT ID
0.771 ± 0.012 OUR EVALUATION	First
0.771 ± 0.012 OUR EVALUATION	Second

CP VIOLATION PARAMETERS

$\mathrm{Re}(\epsilon_{B^0})/(1+|\epsilon_{B^0}|^2)$

CP impurity in B^0_d system. It is obtained from either $a_{\ell\ell}$, the charge asymmetry in like-sign dilepton events or a_{cp}, the time-dependent asymmetry of inclusive B^0 and $\overline{B}^0$ decays.

VALUE (units 10^{-3})	DOCUMENT ID		TECN	COMMENT

• • • We do not use the following data for averages, fits, limits, etc. • • •				
$4 \pm 18 \pm 3$	[577] BEHRENS	00B	CLE2	Repl. by JAFFE 01
< 45	[578] BARTELT	93	CLE2	$e^+e^- \to \Upsilon(4S)$

[572] AUBERT 02K uses the charge asymmetry in like-sign dilepton events.

[573] BARATE 01D measured by investigating time-dependent asymmetries in semileptonic and fully inclusive B^0_d decays.

[574] JAFFE 01 finds $a_{\ell\ell} = 0.013 \pm 0.050 \pm 0.005$ and combines with the previous BEHRENS 00B independent measurement.

[575] Data analyzed using the time-dependent asymmetry of inclusive B^0 decay. The production flavor of B^0 mesons is determined using both the jet charge and the charge of secondary vertex in the opposite hemisphere.

[576] ACKERSTAFF 97U assumes CPT and is based on measuring the charge asymmetry in a sample of B^0 decays defined by lepton and $Q_{\rm hem}$ tags. If CPT is not invoked, $\mathrm{Re}(\epsilon_B) = -0.006 \pm 0.010 \pm 0.006$ is found. The indirect CPT violation parameter is determined to $\mathrm{Im}(\delta B) = -0.020 \pm 0.016 \pm 0.006$.

[577] BEHRENS 00B uses high-momentum lepton tags and partially reconstructed $\overline{B}^0 \to D^{*+}\pi^-$, ρ^- decays to determine the flavor of the B meson.

[578] BARTELT 93 finds $a_{\ell\ell} = 0.031 \pm 0.096 \pm 0.032$ which corresponds to $|a_{\ell\ell}| < 0.18$, which yields the above $|\mathrm{Re}(\epsilon_{B^0})/(1+|\epsilon_{B^0}|^2|$.

$A_{T/CP}$

$A_{T/CP}$ is defined as

$$\frac{P(\overline{B}^0 \to B^0) - P(B^0 \to \overline{B}^0)}{P(\overline{B}^0 \to B^0) + P(B^0 \to \overline{B}^0)},$$

the CPT invariant asymmetry between the oscillation probabilities $P(\overline{B}^0 \to B^0)$ and $P(B^0 \to \overline{B}^0)$.

VALUE	DOCUMENT ID		TECN	COMMENT
0.005 ± 0.012 ± 0.014	[579] AUBERT	02K	BABR	$e^+e^- \to \Upsilon(4S)$

[579] AUBERT 02K uses the charge asymmetry in like-sign dilepton events.

A_{CP} ($B^0 \to K^+\pi^-$)

A_{CP} is defined as

$$\frac{B(\overline{B}^0 \to \overline{f}) - B(B^0 \to f)}{B(\overline{B}^0 \to \overline{f}) + B(B^0 \to f)},$$

the CP-violation charge asymmetry of exclusive B^0 and $\overline{B}^0$ decay.

$\Delta C_{\rho\pi}$ $(B^0 \to \rho^+\pi^-)$

$\Delta C_{\rho\pi}$ describes the asymmetry between the rates $\Gamma(B^0 \to \rho^+\pi^-) + \Gamma(\overline{B}{}^0 \rho^-\pi^+)$ and $\Gamma(B^0 \to \rho^-\pi^+) + \Gamma(\overline{B}{}^0 \to \rho^+\pi^-)$.

sin(2β)

For a discussion of CP violation, see the note on "CP Violation in B Decay Standard Model Predictions" in the B^0 Particle Listings above. sin(2β) is a measure of the CP-violating amplitude in the $B^0_d \to J/\psi(1S)K^0_S$.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. [599] ABE 02Z result is based on 85×10^6 $B\overline{B}$ pairs.

[600] AUBERT 02P result is based on 88×10^6 $B\overline{B}$ pairs.

[601] AFFOLDER 00C uses about 400 $B^0 \to J/\psi(1S)K^0_S$ events. The production flavor of B^0 was determined using three tagging algorithms: a same-side tag, a jet-charge tag, and a soft-lepton tag.

[602] BARATE 00Q uses 23 candidates for $B^0 \to J/\psi(1S)K^0_S$ decays. A combination of jet-charge, vertex-charge, and same-side tagging techniques were used to determine the B^0 production flavor.

[603] ACKERSTAFF 98Z uses 24 candidates for $B^0_d \to J/\psi(1S)K^0_S$ decay. A combination of jet-charge and vertex-charge techniques were used to tag the B^0_d production flavor.

[604] ABE 02U result is based on the same analysis and data sample reported in ABE 01G.

[605] AUBERT 02N result based on the same analysis and data sample reported in AUBERT 01B.

[606] First observation of CP violation in B^0 meson system.

[607] ABE 98U uses 198 ± 17 $B^0_d \to J/\psi(1S)K^0$ events. The production flavor of B^0 was determined using the same side tagging technique.

$B^\pm/B^0$ ADMIXTURE

B DECAY MODES

The branching fraction measurements are for an admixture of B mesons at the $\Upsilon(4S)$. The values quoted assume that $B(\Upsilon(4S) \to B\overline{B}) = 100\%$.

For inclusive branching fractions, *e.g.*, $B \to D^\pm$ anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

$\overline{B}$ modes are charge conjugates of the modes below. Reactions indicate the weak decay vertex and do not include mixing.

	Mode		Fraction (Γ_i/Γ)			Scale factor/ Confidence level
	Semileptonic and leptonic modes					
Γ_1	$B \to e^+\nu_e$ anything	[a]	(10.73	± 0.28)	%	
Γ_2	$B \to \overline{p}e^+\nu_e$ anything		< 5.9			$\times 10^{-4}$ CL=90%
Γ_3	$B \to \mu^+\nu_\mu$ anything	[a]				
Γ_4	$B \to \ell^+\nu_\ell$ anything	[a,b]	(10.73	± 0.28)	%	
Γ_5	$B \to D^-\ell^+\nu_\ell$ anything	[b]	(2.8	± 0.9)	%	
Γ_6	$B \to \overline{D}^0\ell^+\nu_\ell$ anything	[b]	(7.2	± 1.5)	%	
Γ_7	$B \to D^{*-}\ell^+\nu_\ell$ anything					
Γ_8	$B \to D^{*0}\ell^+\nu_\ell$ anything					
Γ_9	$B \to \overline{D}^{**}\ell^+\nu_\ell$	[b,c]	(2.7	± 0.7)	%	
Γ_{10}	$B \to \overline{D}_1(2420)\ell^+\nu_\ell$ anything		(7.4	± 1.6)	$\times 10^{-3}$	
Γ_{11}	$B \to D\pi\ell^+\nu_\ell$ anything + $D^*\pi\ell^+\nu_\ell$ anything		(2.6	± 0.5)	%	S=1.5
Γ_{12}	$B \to D\pi\ell^+\nu_\ell$ anything		(1.5	± 0.6)	%	
Γ_{13}	$B \to D^*\pi\ell^+\nu_\ell$ anything		(1.9	± 0.4)	%	
Γ_{14}	$B \to \overline{D}_2^*(2460)\ell^+\nu_\ell$ anything		< 6.5		$\times 10^{-3}$	CL=95%
Γ_{15}	$B \to D^{*-}\pi^+\ell^+\nu_\ell$ anything		(1.00	± 0.34)	%	
Γ_{16}	$B \to D_s^-\ell^+\nu_\ell$ anything	[b]	< 9		$\times 10^{-3}$	CL=90%
Γ_{17}	$B \to D_s^-\ell^+\nu_\ell K^+$ anything	[b]	< 6		$\times 10^{-3}$	CL=90%
Γ_{18}	$B \to D_s^-\ell^+\nu_\ell K^0$ anything	[b]	< 9		$\times 10^{-3}$	CL=90%
Γ_{19}	$B \to \ell^+\nu_\ell$ noncharmed	[b]				
Γ_{20}	$B \to K^+\ell^+\nu_\ell$ anything	[b]	(6.2	± 0.6)	%	
Γ_{21}	$B \to K^-\ell^+\nu_\ell$ anything	[b]	(10	± 4)	$\times 10^{-3}$	
Γ_{22}	$B \to K^0/\overline{K}^0\ell^+\nu_\ell$ anything	[b]	(4.5	± 0.5)	%	

D, D^*, or D_s modes

Γ_{23}	$B \to$	$D^{\pm}$ anything		(23.5	$\pm$ 1.9	) %

[a] These values are model dependent. See 'Note on Semileptonic Decays' in the B^+ Particle Listings.

[b] An ℓ indicates an e or a μ mode, not a sum over these modes.

[c] D^{**} stands for the sum of the $D(1\,^1P_1)$, $D(1\,^3P_0)$, $D(1\,^3P_1)$, $D(1\,^3P_2)$, $D(2\,^1S_0)$, and $D(2\,^1S_1)$ resonances.

[d] The value is for the sum of the charge states or particle/antiparticle states indicated.

[e] $D^{(*)}\overline{D}^{(*)}$ stands for the sum of $D^*\overline{D}^*$, $D^*\overline{D}$, $D\overline{D}^*$, and $D\overline{D}$.

[f] Inclusive branching fractions have a multiplicity definition and can be greater than 100%.

$B^{\pm}/B^0$ ADMIXTURE BRANCHING RATIOS

$\Gamma(\ell^+\nu_\ell\,\text{anything})/\Gamma_{\text{total}}$ Γ_4/Γ

These branching fraction values are model dependent.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account corrections between the measurements.

• • • We do not use the following data for averages, fits, limits, etc. • • •				
0.108 ±0.002 ±0.0056	[1] HENDERSON	92	CLEO	$e^+e^- \to \Upsilon(4S)$

[1] HENDERSON 92 measurement employs e and μ. The systematic error contains 0.004 in quadrature from model dependence. The authors average a variation of the Isgur, Scora, Grinstein, and Wise model with that of the Altarelli-Cabibbo-Corbo-Maiani-Martinelli model for semileptonic decays to correct the acceptance.

$\Gamma(e^+\nu_e\,\text{anything})/\Gamma_{\text{total}}$ Γ_1/Γ

These branching fraction values are model dependent.

"OUR EVALUATION" is an average using rescaled values of the data listed below. [2] Uses the high-momentum lepton tag method. They also report $|V_{cb}| = 0.0423 \pm 0.0007(\text{exp}) \pm 0.0020(\text{theo.})$.

[3] Uses the high-momentum lepton tag method. ABE 02Y also reports $|V_{cb}| = 0.0408 \pm 0.0010(\text{exp}) \pm 0.0025(\text{theo.})$. The second error is due to uncertainties of theoretical inputs.

[4] BARISH 96B analysis performed using tagged semileptonic decays of the B. This technique is almost model independent for the lepton branching ratio.

[5] ALBRECHT 93H analysis performed using tagged semileptonic decays of the B. This technique is almost model independent for the lepton branching ratio.

[6] YANAGISAWA 91 also measures an average semileptonic branching ratio at the $\Upsilon(5S)$ of 9.6–10.5% depending on assumptions about the relative production of different B meson species.

[7] ALBRECHT 90H uses the model of ALTARELLI 82 to correct over all lepton momenta. 0.099 ± 0.006 is obtained using ISGUR 89B.

[8] Using data above $p(e) = 2.4$ GeV, WACHS 89 determine $\sigma(B \to e\nu\text{up})/\sigma(B \to e\nu\text{charm}) < 0.065$ at 90% CL.

[9] Ratio $\sigma(b \to e\nu\text{up})/\sigma(b \to e\nu\text{charm}) < 0.055$ at CL = 90%.

$\Gamma(\mu^+\nu_\mu\,\text{anything})/\Gamma_{\text{total}}$ Γ_3/Γ

• • • We do not use the following data for averages, fits, limits, etc. • • •						
<0.028	95		[17] BARISH	95	CLE2	$e^+e^- \to \Upsilon(4S)$

[16] ALBRECHT 93 assumes the GISW model to correct for unseen modes. Using the BHKT model, the result becomes 0.023 ± 0.006 ± 0.004. Assumes $B(D^{*+} \to D^0\pi^+) = 68.1\%$, $B(D^0 \to K^-\pi^+) = 3.65\%$, $B(D^0 \to K^-\pi^+\pi^-\pi^+) = 7.5\%$. We have taken their average e and μ value.

[17] BARISH 95 use $B(D^0 \to K^-\pi^+) = (3.91 \pm 0.08 \pm 0.17)\%$, assume all nonresonant channels are zero, and use GISW model for relative abundances of D^{**} states.

$\Gamma(\overline{D}_1(2420)\ell^+\nu_\ell\,\text{anything})/\Gamma_{\text{total}}$ Γ_{10}/Γ

VALUE	DOCUMENT ID		TECN	COMMENT
0.0074±0.0016	[18] BUSKULIC	97B	ALEP	$e^+e^- \to Z$
• • • We do not use the following data for averages, fits, limits, etc. • • •				
seen	[19] BUSKULIC	95B	ALEP	Repl. by BUSKULIC 97B

[18] BUSKULIC 97B assumes $B(D_1(2420) \to D^*\pi) = 1$, $B(D_1(2420) \to D^*\pi^\pm) = 2/3$, and $B(b \to B) = 0.378 \pm 0.022$.

[19] BUSKULIC 95B reports $f_B \times B(B \to \overline{D}_1(2420)^0\ell^+\nu_\ell\,\text{anything}) \times B(\overline{D}_1(2420)^0 \to \overline{D}^*(2010)^-\pi^+) = (2.04 \pm 0.58 \pm 0.34)10^{-3}$, where f_B is the production fraction for a single B charge state.

$[\Gamma(D\pi\ell^+\nu_\ell\,\text{anything}) + \Gamma(D^*\pi\ell^+\nu_\ell\,\text{anything})]/\Gamma_{\text{total}}$ Γ_{11}/Γ

VALUE	DOCUMENT ID		TECN	COMMENT
0.026 ±0.005 OUR AVERAGE Error includes scale factor of 1.5.				
0.0340±0.0052±0.0032	[20] ABREU	00R	DLPH	$e^+e^- \to Z$
0.0226±0.0029±0.0033	[21] BUSKULIC	97B	ALEP	$e^+e^- \to Z$

[20] Assumes no contribution from B_s and b baryons. Further assumes contributions from single pion ($D\pi$ and $D^*\pi$) states only, allowing isospin conservation to relate the relative π^0 and π^+ rates.

[21] BUSKULIC 97B assumes $B(b \to B) = 0.378 \pm 0.022$ and uses isospin invariance by assuming that all observed $D^0\pi^+$, $D^{*0}\pi^+$, $D^+\pi^-$, and $D^{*+}\pi^-$ are from D^{**} states. A correction has been applied to account for the production of B_s^0 and Λ_b^0.

[28] ALBRECHT 94C find $\Gamma(b \to c)/\Gamma(b \to \text{all}) = 0.99 \pm 0.02 \pm 0.04$.

[29] BARTELT 93B (CLEO II) measures an excess of $107 \pm 15 \pm 11$ leptons in the lepton momentum interval 2.3–2.6 GeV/c which is attributed to $b \to u\ell\nu_\ell$. This corresponds to a model-dependent partial branching ratio ΔB_{ub} between $(1.15 \pm 0.16 \pm 0.15) \times 10^{-4}$, as evaluated using the KS model (KOERNER 88), and $(1.54 \pm 0.22 \pm 0.20) \times 10^{-4}$ using the ACCMM model (ARTUSO 93). The corresponding values of $|V_{ub}|/|V_{cb}|$ are 0.056 ± 0.006 and 0.076 ± 0.008, respectively.

[30] ALBRECHT 91C result supersedes ALBRECHT 90. Two events are fully reconstructed providing evidence for the $b \to u$ transition. Using the model of ALTARELLI 82, they obtain $|V_{ub}/V_{cb}| = 0.11 \pm 0.012$ from 77 leptons in the 2.3–2.6 GeV momentum range.

[31] FULTON 90 observe 76 ± 20 excess e and μ (lepton) events in the momentum interval $p = 2.4$–2.6 GeV signaling the presence of the $b \to u$ transition. The average branching ratio, $(1.8 \pm 0.4 \pm 0.3) \times 10^{-4}$, corresponds to a model-dependent measurement of approximately $|V_{ub}/V_{cb}| = 0.1$ using $B(b \to c\ell\nu) = 10.2 \pm 0.2 \pm 0.7\%$.

[32] ALBRECHT 90 observes 41 ± 10 excess e and μ (lepton) events in the momentum interval $p = 2.3$–2.6 GeV signaling the presence of the $b \to u$ transition. The events correspond to a model-dependent measurement of $|V_{ub}/V_{cb}| = 0.10 \pm 0.01$.

[33] The quoted possible limits range from 0.018 to 0.04 for the ratio, depending on which model or momentum range is chosen. We select the most conservative limit they have calculated. This corresponds to a limit on $|V_{ub}|/|V_{cb}| < 0.20$. While the endpoint technique employed is more robust than their previous results in CHEN 84, these results do not provide a numerical improvement in the limit.

[72] AUBERT 03F also reports the momentum distribution and helicity of $J/\psi \to \ell^+\ell^-$ in the $\Upsilon(4S)$ center-of-mass frame.

[73] MASCHMANN 90 reports 1.12 ± 0.33 ± 0.25 for $B(J/\psi(1S) \to e^+e^-) = 0.069 \pm 0.009$. We rescale to our best value $B(J/\psi(1S) \to e^+e^-) = (5.93 \pm 0.10) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

[74] ALBRECHT 87D reports 1.07 ± 0.16 ± 0.22 for $B(J/\psi(1S) \to e^+e^-) = 0.069 \pm 0.009$. We rescale to our best value $B(J/\psi(1S) \to e^+e^-) = (5.93 \pm 0.10) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. ALBRECHT 87D find the branching ratio for J/ψ not from $\psi(2S)$ to be 0.0081 ± 0.0023.

[75] ALAM 86 reports 1.09 ± 0.16 ± 0.21 for $B(J/\psi(1S) \to \mu^+\mu^-) = 0.074 \pm 0.012$. We rescale to our best value $B(J/\psi(1S) \to \mu^+\mu^-) = (5.88 \pm 0.10) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

[76] BALEST 95B reports 1.12 ± 0.04 ± 0.06 for $B(J/\psi(1S) \to e^+e^-) = 0.0599 \pm 0.0025$. We rescale to our best value $B(J/\psi(1S) \to e^+e^-) = (5.93 \pm 0.10) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.. They measure $J/\psi(1S) \to e^+e^-$ and $\mu^+\mu^-$ and use PDG 1994 values for the branching fractions. The rescaling is the same for either mode so we use e^+e^-.

[77] Statistical and systematic errors were added in quadrature. ALBRECHT 85H also report a CL = 90% limit of 0.007 for $B \to J/\psi(1S) + X$ where $m_X < 1$ GeV.

[78] Dimuon and dielectron events used.

• • • We do not use the following data for averages, fits, limits, etc. • • •				
2.32 ± 0.57 ± 0.35	ALAM	95	CLE2	Repl. by CHEN 01C

[116] ABE 01F reports their systematic errors $\pm 0.42^{+0.50}_{-0.54}$, where the second error is due to the theoretical uncertainty. We combine them in quadrature.

[117] We have combined the experimental systematic theoretical uncertainties in quadrature. Also determined the first and second moments of the photon energy spectrum above 2.0 GeV: $\langle E_\gamma \rangle = 2.346 \pm 0.032 \pm 0.011$ GeV and $\langle E_\gamma^2 \rangle - \langle E_\gamma \rangle^2 = 0.0226 \pm 0.0066 \pm 0.0020$ GeV^2.

• • • We do not use the following data for averages, fits, limits, etc. • • •						
< 0.08	2		[119] ALBRECHT	95D	ARG	$e^+e^- \to \Upsilon(4S)$

[118] COAN 98 uses D-ℓ correlation.

[119] ALBRECHT 95D use full reconstruction of one B decay as tag. Two candidate events for charmless B decay can be interpreted as either $b \to s$gluon or $b \to u$ transition. If interpreted as $b \to s$gluon they find a branching ratio of ~ 0.026 or the upper limit quoted above. Result is highly model dependent.

$B^{\pm}/B^0/B_s^0/b$-baryon ADMIXTURE

$B^{\pm}/B^0/B_s^0/b$-baryon ADMIXTURE MEAN LIFE

Each measurement of the B mean life is an average over an admixture of various bottom mesons and baryons which decay weakly. Different techniques emphasize different admixtures of produced particles, which could result in a different B mean life.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account corrections between the measurements and asymmetric lifetime errors, but ignores the small differences due to different techniques.

[1] Measured using inclusive $J/\psi(1S) \to \mu^+\mu^-$ vertex.
[2] ACCIARRI 98 uses inclusively reconstructed secondary vertex and lepton impact parameter.
[3] ACKERSTAFF 97F uses inclusively reconstructed secondary vertices.
[4] BUSKULIC 96F analyzed using 3D impact parameter.
[5] ABE,K 95B uses an inclusive topological technique.
[6] ABREU 94L uses charged particle impact parameters. Their result from inclusively reconstructed secondary vertices is superseded by ABREU 96E.
[7] ACTON 93L and ADRIANI 93K analyzed using lepton (e and μ) impact parameter at Z.
[8] BUSKULIC 93O analyzed using dipole method.
[9] Combines ABREU 96E secondary vertex result with ABREU 94L impact parameter result.
[10] From proper time distribution of $b \to J/\psi(1S)$ anything.
[11] ABE 93J analyzed using $J/\psi(1S) \to \mu\mu$ vertices.
[12] ABREU 93D data analyzed using $D/D^*\ell$ anything event vertices.
[13] ABREU 93G data analyzed using charged and neutral vertices.
[14] ACTON 93C analysed using $D/D^*\ell$ anything event vertices.
[15] ABREU 92 is combined result of muon and hadron impact parameter analyses. Hadron tracks gave $(12.7 \pm 0.4 \pm 1.2) \times 10^{-13}$ s for an admixture of B species weighted by production fraction and mean charge multiplicity, while muon tracks gave $(13.0 \pm 1.0 \pm 0.8) \times 10^{-13}$ s for an admixture weighted by production fraction and semileptonic branching fraction.
[16] ACTON 92 is combined result of muon and electron impact parameter analyses.
[17] BUSKULIC 92F uses the lepton impact parameter distribution for data from the 1991 run.
[18] BUSKULIC 92G use $J/\psi(1S)$ tags to measure the average b lifetime. This is comparable to other methods only if the $J/\psi(1S)$ branching fractions of the different b-flavored hadrons are in the same ratio.
[19] Using $Z \to e^+X$ or μ^+X, ADEVA 91H determined the average lifetime for an admixture of B hadrons from the impact parameter distribution of the lepton.
[20] Using $Z \to J/\psi(1S)X$, $J/\psi(1S) \to \ell^+\ell^-$, ALEXANDER 91G determined the average lifetime for an admixture of B hadrons from the decay point of the $J/\psi(1S)$.
[21] Using $Z \to eX$ or μX, DECAMP 91C determines the average lifetime for an admixture of B hadrons from the signed impact parameter distribution of the lepton.
[22] HAGEMANN 90 uses electrons and muons in an impact parameter analysis.
[23] LYONS 90 combine the results of the B lifetime measurements of ONG 89, BRAUNSCHWEIG 89B, KLEM 88, and ASH 87, and JADE data by private communication. They use statistical techniques which include variation of the error with the mean life, and possible correlations between the systematic errors. This result is not independent of the measured results used in our average.
[24] We have combined an overall scale error of 15% in quadrature with the systematic error of ±0.7 to obtain ±2.1 systematic error.
[25] Statistical and systematic errors were combined by BROM 87.

$|\Delta\tau_b|/\tau_{b,\overline{b}}$

$\tau_{b,\overline{b}}$ and $|\Delta\tau_b|$ are the mean life average and difference between b and $\overline{b}$ hadrons.

VALUE	*DOCUMENT ID*		*TECN*	*COMMENT*
−0.001 ± 0.012 ± 0.008	[29] ABBIENDI	99J	OPAL	$e^+e^- \to Z$

[29] Data analyzed using both the jet charge and the charge of secondary vertex in the opposite hemisphere.

$\overline{b}$ PRODUCTION FRACTIONS AND DECAY MODES

The branching fraction measurements are for an admixture of B mesons and baryons at energies above the $\Upsilon(4S)$. Only the highest energy results (LEP, Tevatron, S$p\overline{p}$S) are used in the branching fraction averages. In the following, we assume that the production fractions are the same at the LEP and at the Tevatron.

For inclusive branching fractions, *e.g.*, $B \rightarrow D^{\pm}$ anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

The modes below are listed for a $\overline{b}$ initial state. b modes are their charge conjugates. Reactions indicate the weak decay vertex and do not include mixing.

Mode	Fraction (Γ_j/Γ)	Scale factor/ Confidence level

PRODUCTION FRACTIONS

The production fractions for weakly decaying b-hadrons at high energy have been calculated from the best values of mean lives, mixing parameters, and branching fractions in this edition by the Heavy Flavor Averaging Group (HFAG) as described in the note "B^0-$\overline{B}^0$ Mixing" in the B^0 Particle Listings. Values assume

$$B(\overline{b} \rightarrow B^+) = B(\overline{b} \rightarrow B^0)$$
$$B(\overline{b} \rightarrow B^+) + B(\overline{b} \rightarrow B^0) + B(\overline{b} \rightarrow B_s^0) + B(b \rightarrow b\text{-baryon}) = 100\ \%.$$

The notation for production fractions varies in the literature (f_d, d_{B^0}, $f(b \rightarrow \overline{B}^0)$, $Br(b \rightarrow \overline{B}^0)$). We use our own branching fraction notation here, $B(\overline{b} \rightarrow B^0)$.

[36] Uses the combination of lepton transverse momentum spectrum and the correlation between the charge of the lepton and opposite jet charge. The first error is statistic and the second error is the total systematic error including the modeling.
[37] The experimental systematic and model uncertainties are combined in quadrature.
[38] ABBIENDI 00E result is determined by comparing the distribution of several kinematic variables of leptonic events in a lifetime tagged $Z \to b\overline{b}$ sample using artificial neural network techniques. The first error is statistic; the second error is the total systematic error.
[39] ACCIARRI 00 result obtained from a combined fit of $R_b = \Gamma(Z \to b\overline{b})/\Gamma(Z \to \text{hadrons})$ and $B(b \to \ell\nu X)$, using double-tagging method.
[40] ACCIARRI 96C result obtained by a fit to the single lepton spectrum.
[41] Assumes Standard Model value for R_B.
[42] ABREU 95D give systematic errors ±0.0019 (model) and 0.0012 (R_c). We combine these in quadrature.
[43] BUSKULIC 94G uses e and μ events. This value is from a global fit to the lepton p and p_T (relative to jet) spectra which also determines the b and c production fractions, the fragmentation functions, and the forward-backward asymmetries. This branching ratio depends primarily on the ratio of dileptons to single leptons at high p_T, but the lower p_T portion of the lepton spectrum is included in the global fit to reduce the model dependence. The model dependence is ±0.0026 and is included in the systematic error.
[44] ABREU 93C event count includes ee events. Combining ee, $\mu\mu$, and $e\mu$ events, they obtain 0.100 ± 0.007 ± 0.007.
[45] AKERS 93B analysis performed using single and dilepton events.

χ_b AT HIGH ENERGY

For a discussion of B-$\overline{B}$ mixing, see the note on B^0-$\overline{B}^0$ Mixing" in the B^0 Particle Listings.

χ_b is the average B-$\overline{B}$ mixing parameter at high-energy $\chi_b=f'_d\chi_d+f'_s\chi_s$ where f'_d and f'_s are the fractions of B^0 and B_s^0 hadrons in an unbiased sample of semileptonic b-hadron decays.

"OUR EVALUATION" is an average of the data listed below. Performed by the LEP Electroweak Working Group as described in the "Note on the Z boson" in the Z Particle Listings.

[130] The average B mixing parameter is determined simultaneously with b and c forward-backward asymmetries in the fit.

[131] The experimental systematic and model uncertainties are combined in quadrature.

[132] ACCIARRI 99D uses maximum-likelihood fits to extract χ_b as well as the A_{FB}^b in $Z\to b\overline{b}$ events containing prompt leptons.

[133] Uses di-muon events.

[134] This ABREU 94J result is from 5182 $\ell\ell$ and 279 $\Lambda\ell$ events. The systematic error includes 0.004 for model dependence.

[135] BUSKULIC 94G data analyzed using ee, $e\mu$, and $\mu\mu$ events.

[136] BUSKULIC 92B uses a jet charge technique combined with electrons and muons.

[137] ABE 91G measurement of χ is done with $e\mu$ and ee events.

[138] ALBAJAR 91D measurement of χ is done with dimuons.

[139] ALEXANDER 96 uses a maximum likelihood fit to simultaneously extract χ as well as the forward-backward asymmetries in $e^+e^-\to Z\to b\overline{b}$ and $c\overline{c}$.

[140] UENO 96 extracted χ from the energy dependence of the forward-backward asymmetry.

[141] ABREU 94F uses the average electric charge sum of the jets recoiling against a b-quark jet tagged by a high p_T muon. The result is for $\overline{\chi}=f_d\chi_d+0.9f_s\chi_s$.

[142] This ABREU 94J result combines $\ell\ell$, $\Lambda\ell$, and jet-charge ℓ (ABREU 94F) analyses. It is for $\overline{\chi}=f_d\chi_d+0.96f_s\chi_s$.

[143] ALBAJAR 94 uses dimuon events. Not independent of ALBAJAR 91D.

Meson Particle Listings

$B^{\pm}/B^0/B_s^0/b$-baryon ADMIXTURE, V_{cb} and V_{ub} CKM Matrix Elements

[144] ABREU 93C data analyzed using ee, $e\mu$, and $\mu\mu$ events.
[145] AKERS 93B analysis performed using dilepton events.
[146] ACTON 92C uses electrons and muons. Superseded by AKERS 93B.
[147] ADEVA 92C uses electrons and muons.
[148] DECAMP 91 done with opposite and like-sign dileptons. Superseded by BUSKULIC 92B.
[149] ADEVA 90P measurement uses ee, $\mu\mu$, and $e\mu$ events from 118k events at the Z. Superseded by ADEVA 92C.
[150] These experiments are not in the average because the combination of B_s and B_d mesons which they see could differ from those at higher energy.
[151] The WEIR 90 measurement supersedes the limit obtained in SCHAAD 85. The 90% CL are 0.06 and 0.38.
[152] ALBAJAR 87C measured $\chi = (\overline{B}^0 \rightarrow B^0 \rightarrow \mu^+ X)$ divided by the average production weighted semileptonic branching fraction for B hadrons at 546 and 630 GeV.
[153] Limit is average probability for hadron containing B quark to produce a positive lepton.

V_{cb} and V_{ub} CKM Matrix Elements

OMITTED FROM SUMMARY TABLE

DETERMINATION OF $|V_{cb}|$

Updated December 2003 by M. Artuso (Syracuse University) and E. Barberio (University of Melbourne).

I. Introduction

In the framework of the Standard Model, the quark sector is characterized by a rich pattern of flavor-changing transitions, described by the Cabibbo-Kobayashi-Maskawa (CKM) matrix (see CKM review [1]). This report focuses on the quark mixing parameter $|V_{cb}|$.

Two different methods have been used to extract this parameter from data: the **exclusive** measurement, where $|V_{cb}|$ is extracted by studying $B \to D^{\star}\ell\nu$ or $B \to D\ell\nu$ decay processes; and the **inclusive** measurement, which uses the semileptonic width of b-hadron decays ($B \to X\ell\overline{\nu}$). Theoretical estimates play a crucial role in extracting $|V_{cb}|$, and an understanding of their uncertainties is very important.

II. $|V_{cb}|$ determination from exclusive channels

The exclusive $|V_{cb}|$ determination is obtained studying $B \to D^{\star}\ell\nu$ or $B \to D\ell\nu$ decays, using Heavy Quark Effective Theory (HQET), an exact theory in the limit of infinite quark masses. Currently, the $B \to D\ell\nu$ transition provides a less precise value, and is used as a check.

The decay $B \to D^{\star}\ell\nu$ in HQET: HQET predicts that the differential partial decay width for this process, $d\Gamma/dw$, is related to $|V_{cb}|$ through:

$$\frac{d\Gamma}{dw}(B \to D^{\star}\ell\nu) = \frac{G_F^2|V_{cb}|^2}{48\pi^3}\mathcal{K}(w)\mathcal{F}(w)^2, \qquad (1)$$

where w is the inner product of the B and $D^{\star}$ meson 4-velocities, $\mathcal{K}(w)$ is a known phase-space factor, and the form factor $\mathcal{F}(w)$ is generally expressed as the product of a normalization constant, $\mathcal{F}(1)$, and a function, $g(w)$, constrained by experimental studies of the helicity amplitudes characterizing this decay [2] and dispersion relations [3].

There are several different corrections to the infinite mass value $\mathcal{F}(1) = 1$ [4]:

$$\mathcal{F}(1) = \eta_{\rm QED}\eta_A\left[1 + \delta_{1/m_Q^2} + ...\right], \qquad (2)$$

here and in the following discussion of exclusive semileptonic decays, m_Q is a generic notation for m_c or m_b. By virtue

of Luke's theorem [5], the first term in the non-perturbative expansion in powers of $1/m_Q$ vanishes. QED corrections up to leading-logarithmic order give $\eta_{\rm QED} \approx 1.007$ [6] and QCD radiative corrections to two loops give $\eta_A = 0.960 \pm 0.007$ [7]. Different estimates of the $1/m_Q^2$ corrections, involving terms proportional to $1/m_b^2$, $1/m_c^2$, and $1/(m_b m_c)$, have been performed in a quark model [8,10], with OPE sum rules [11], and, more recently, with an HQET based lattice gauge calculation [12]. The value from this quenched lattice HQET calculation is $\mathcal{F}(1) = 0.913^{+0.024}_{-0.017} \pm 0.016^{+0.003}_{-0.014}{}^{+0.000}_{-0.016}{}^{+0.006}_{-0.014}$. The errors quoted reflect the statistical accuracy, the matching error, the lattice finite size, the uncertainty in the quark masses, and an estimate of the error induced by the quenched approximation, respectively. The central value obtained with OPE sum rules is similar, $0.900 \pm 0.015 \pm 0.025 \pm 0.025$ [11], where the three errors parameterize different sources of theoretical uncertainty. Here we will use $\mathcal{F}(1) = 0.91 \pm 0.04$ [13], a value that is consistent with all the three determinations discussed above. We have chosen not to rely solely on the value of $\mathcal{F}(1)$ coming from the lattice, because of the difficulties of quantifying the uncertainty induced by the quenched approximation. Recent developments give confidence that this limitation will be overcome in the next few years [15]. Technical advances, such as new improved staggered discretization, may lead to precise value of some "gold-plated" lattice quantities, such as $\mathcal{F}(1)$ in $B \to D^\star \ell \overline{\nu}$. The stated theoretical accuracy will be checked by comparing predicted and measured values of a large number of non-perturbative quantities [17].

The analytical expression of $g(w)$, the universal form factor related to the Isgur-Wise function [18], is not known a-priori, and this introduces an additional uncertainty in the determination of $\mathcal{F}(1)|V_{cb}|$. First measurements of $|V_{cb}|$ were performed assuming a linear approximation for $g(w)$. It has been shown [19] that this assumption is not justified, and that linear fits systematically underestimate the extrapolation at zero recoil ($w = 1$) by about 3%. Most of this effect is related to the curvature of the form factor, and does not depend strongly upon the details of the chosen non-linear shape [19]. All recent published results use a non-linear shape for $g(w)$, approximated with an expansion near $w = 1$ [20]. $g(w)$ is parameterized in terms of the variable ρ^2, which is the slope of the form factor at zero recoil given in Ref. 20.

Experimental techniques to study the decay $B \to D^\star \ell \nu$:

The decay $B \to D^\star \ell \nu$ has been studied in experiments performed at center-of-mass energies equal to the $\Upsilon(4S)$ mass and the Z^0 mass. At the $\Upsilon(4S)$, experiments have the advantage that the w resolution is quite good. The dominant systematic uncertainties arise from background estimation and from the slow pion efficiency evaluation. This efficiency for charged pions is very low near w=1 and increases rapidly as w increases, while for neutral pions it drops slowly. CLEO [22] studies both $D^{\star +}$ and $D^{\star o}$ channels, while Belle [23] and BaBar [24] have so far presented only results based on $D^{\star +} \ell \nu$. In addition, kinematic constraints enable $\Upsilon(4S)$ experiments to identify the final state, including the $D^\star$, without a large contamination from the poorly known semileptonic decays including a hadronic system heavier than $D^\star$, commonly identified as '$D^{\star\star}$'. At LEP, B's are produced with a large momentum (about 30 GeV on average). The large boost produces a broadening in the reconstructed ν 4-momentum, needed to determine w, thus giving a relatively poor resolution and limited physics background rejection capabilities. On the other hand, LEP experiments benefit from an efficiency that is only mildly dependent upon w.

Experiments determine the product $(\mathcal{F}(1) \cdot |V_{cb}|)^2$ by fitting the measured $d\Gamma/dw$ distribution. Measurements have been published by CLEO [22], Belle [23], DELPHI [25], ALEPH [26], and OPAL [27]. Most recently, a preliminary measurement from BaBar has been presented [24]. At LEP, the dominant source of systematic error is the uncertainty on the contribution to $d\Gamma/dw$ from semileptonic B decays with final states including a hadron system heavier than the $D^\star$. This component includes both narrow orbitally excited charmed mesons and non-resonant or broad species. The existence of narrow resonant states is well established [1], and a signal of a broad resonance has been seen by CLEO [28], and, most recently, by Belle [29], but the decay characteristics of these states in b-hadron semileptonic decays have large uncertainties. The average of ALEPH [30], Belle [33], CLEO [31], and DELPHI [32] narrow state branching fractions show that the ratio $R_{\star\star} = \dfrac{\mathrm{B}(\overline{B} \to D_2^\star \ell \overline{\nu})}{\mathrm{B}(\overline{B} \to D_1 \ell \overline{\nu})}$ is smaller than one (< 0.6 at 95% C.L. [34]), in disagreement with HQET models where an infinite quark mass is assumed [35], but in agreement with models which take into account finite quark mass corrections [36]. Hence, LEP experiments use the treatment of narrow $D^{\star\star}$ proposed in [36], which accounts for $\mathcal{O}(1/m_c)$ corrections and provides several possible approximations of the form factors that depend on five different expansion schemes, and on three input parameters. To calculate the systematic errors, each proposed scheme is tested, with the relevant input parameters varied over a range consistent with the experimental limit on $R_{\star\star}$. The quoted systematic error is the maximal difference from the central value obtained with this method. Broad resonances or other non-resonant terms may not be modelled correctly with this approach.

To combine the published data, the central values and the errors of $\mathcal{F}(1)|V_{cb}|$ and ρ^2 are re-scaled to the same set of input parameters and their quoted uncertainties [21]. The $\mathcal{F}(1)|V_{cb}|$ values used for this average are extracted using the parametrization in Ref. 22, based on the experimental determinations of the vector and axial form factor ratios R_1 and R_2 [38]. The LEP data, which originally used theoretical values for these ratios, are re-scaled accordingly [37]. Table 1 summarizes the corrected data. The averaging procedure [37] takes into account statistical and systematic correlations between $\mathcal{F}(1)|V_{cb}|$ and ρ^2. Averaging the measurements in Table 1, we get:

$$\mathcal{F}(1)|V_{cb}| = (38.2 \pm 0.5 \pm 0.9) \times 10^{-3}$$

and

$$\rho^2 = 1.56 \pm 0.05 \pm 0.13, \qquad (3)$$

with χ^2 per degree of freedom of 22/12. The error ellipses for the corrected measurements and for the world average are shown in Figure 1. They are the product between the 1 σ error of $\mathcal{F}(1)|V_{cb}|$, ρ^2, and the correlation between the two. Since this is a 2 parameter fit, the ellipses correspond to about 37% CL contours. The χ^2 per degree of freedom is 1.8. We have not rescaled the errors.

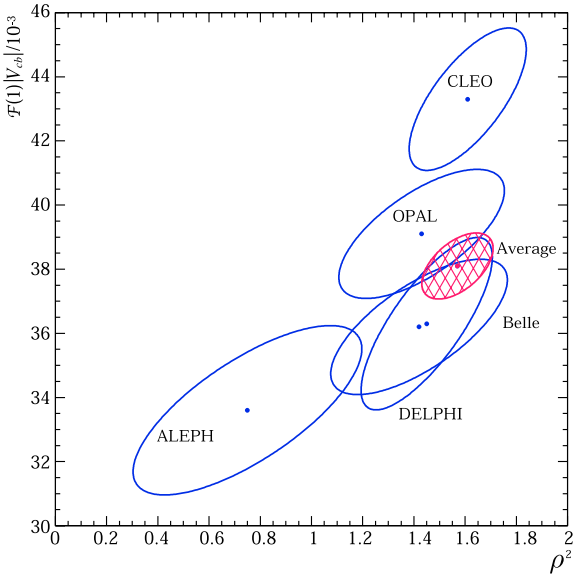

Figure 1: The error ellipses for the corrected measurements and world average for $\mathcal{F}(1)|V_{cb}|$ vs ρ^2. The ellipses are the product between the 1 σ error of $\mathcal{F}(1)|V_{cb}|$, ρ^2, and the correlation between the two. Consequently the ellipses correspond to about 37% CL. See full-color version on color pages at end of book.

The main contributions to the $\mathcal{F}(1)|V_{cb}|$ systematic error are from the uncertainty on the $B \to D^{**}\ell\nu$ shape and B($b \to B_d$), fully correlated among the LEP experiments, the branching fraction of D and $D^\star$ decays, fully correlated among all the experiments, and the slow pion reconstruction from Belle and CLEO which are uncorrelated, The main contribution to the ρ^2 systematic error is from the uncertainties in the measured values of R_1 and R_2, fully correlated among experiments. Because of the large contribution of this uncertainty to the non-diagonal terms of the covariance matrix, the averaged ρ^2 is higher than one would naively expect.

Using $\mathcal{F}(1) = 0.91 \pm 0.04$ [13], we get $|V_{cb}| = (42.0 \pm 1.1_{\rm exp} \pm 1.8_{\rm theo}) \times 10^{-3}$. The dominant error is theoretical, and there are good prospects to reduce it in the next few years [14], [17].

Table 1: Experimental results from $B \to D^\star\ell\nu$ analyses after the correction to common inputs and world average. The LEP numbers are corrected to use R_1 and R_2 from CLEO data. ρ^2 is the slope of the form factor at zero recoil as defined in Ref. 20. $\rm Corr_{stat}$ is the statistical correlation between $\mathcal{F}(1)|V_{cb}|$ and ρ^2. (* Average of two measurements.)

Exp.	$\mathcal{F}(1)\lvert V_{cb}\rvert(\times 10^3)$	ρ^2	$\rm Corr_{stat}$
ALEPH	$33.6 \pm 2.1 \pm 1.6$	$0.75 \pm 0.25 \pm 0.37$	94%
DELPHI*	$36.2 \pm 1.1 \pm 1.8$	$1.42 \pm 0.10 \pm 0.33$	92%
OPAL*	$39.1 \pm 0.9 \pm 1.8$	$1.43 \pm 0.12 \pm 0.31$	89%
Belle	$36.3 \pm 1.9 \pm 1.9$	$1.45 \pm 0.16 \pm 0.20$	91%
CLEO	$43.3 \pm 1.3 \pm 1.8$	$1.61 \pm 0.09 \pm 0.21$	87%
BaBar	$34.1 \pm 0.2 \pm 1.3$	$1.23 \pm 0.02 \pm 0.28$	92%
World average	$38.2 \pm 0.5 \pm 0.9$	$1.56 \pm 0.05 \pm 0.13$	53%

The decay $B \to D\ell\nu$: The study of the decay $B \to D\ell\nu$ poses new challenges both from the theoretical and experimental point of view.

The differential decay rate for $B \to D\ell\nu$ can be expressed as:

$$\frac{d\Gamma_D}{dw}(B \to D\ell\nu) = \frac{G_F^2|V_{cb}|^2}{48\pi^3}\mathcal{K}_{\mathcal{D}}(w)\mathcal{G}(w)^2, \qquad (4)$$

where w is the inner product of the B and D meson 4-velocities, $\mathcal{K}_{\mathcal{D}}(w)$ is the phase space, and the form factor $\mathcal{G}(w)$ is generally expressed as the product of a normalization factor, $\mathcal{G}(1)$, and a function, $g_D(w)$, constrained by dispersion relations [3].

The strategy to extract $\mathcal{G}(1)|V_{cb}|$ is identical to that used for the $B \to D^\star\ell\nu$ decay. However, in this case there is no suppression of $1/m_Q$ (*i.e.*, no Luke theorem) and corrections and QCD effects on $\mathcal{G}(1)$ are calculated with less accuracy than $\mathcal{F}(1)$ [39,40]. Moreover, $d\Gamma_D/dw$ is more heavily suppressed near $w = 1$ than $d\Gamma_{D^*}/dw$, due to the helicity mismatch between initial and final states. This channel is also much more challenging from the experimental point of view as it is hard to isolate from the dominant $B \to D^\star\ell\nu$ background, as well as from fake D–ℓ combinations. Thus, the extraction of $|V_{cb}|$ from this channel is less precise than the one from the $B \to D^\star\ell\nu$ decay. Nevertheless, the $B \to D\ell\nu$ channel provides a consistency check, and allows a test of heavy-quark symmetry [40] through the measurement of the form factor $\mathcal{G}(w)$, as HQET predicts the ratio $\mathcal{G}(w)/\mathcal{F}(w)$ to be very close to one.

Belle [41] and ALEPH [26] studied the $\overline{B}^0 \to D^+\ell^-\overline{\nu}$ channel, while CLEO [42] studied both $B^+ \to D^0\ell^+\overline{\nu}$ and $\overline{B}^0 \to D^+\ell^-\overline{\nu}$ decays. Averaging the data in Table 2 [37], we get $\mathcal{G}(1)|V_{cb}| = (41.8 \pm 3.7) \times 10^{-3}$ and $\rho_D^2 = 1.15 \pm 0.16$, where ρ_D^2 is the slope of the form factor at zero recoil given in Ref. 20.

Table 2: Experimental results after the correction to common inputs and world average. ρ_D^2 is the slope of the form factor at zero recoil given in Ref. 20.

Exp.	$\mathcal{G}(1)\lvert V_{cb}\rvert(\times 10^3)$	ρ_D^2
ALEPH	$39.3 \pm 10.0 \pm 6.5$	$0.97 \pm 0.98 \pm 0.38$
Belle	$41.8 \pm 4.4 \pm 5.2$	$1.12 \pm 0.22 \pm 0.14$
CLEO	$44.4 \pm 5.8 \pm 3.5$	$1.27 \pm 0.25 \pm 0.14$
World average	$41.8 \pm 2.5 \pm 2.7$	$1.15 \pm 0.13 \pm 0.09$

The theoretical predictions for $\mathcal{G}(1)$ are consistent: 1.03 ± 0.07 [43], and 1.02 ± 0.08 [40]. A quenched lattice calculation gives $\mathcal{G}(1) = 1.058^{+0.021}_{-0.017}$ [44], where the errors do not include the uncertainties induced by the quenching approximation and lattice spacing. An unquenched value should be available in the next few years [15]. A recent study of the decay $B \to D\ell\overline{\nu}$ in the context of heavy quark sum rules [16] argues that this channel can provide an alternative very precise determination of $|V_{cb}|$. *Ref. [16] uses heavy quark sum rules to relate exclusive form factors and inclusive semileptonic width and argues that in the approximation $\mu_\pi^2 - \mu_G^2 << \mu_\pi^2$, many power corrections vanish to all orders in $1/m_Q$. The parameter μ_π^2 represents the expectation value of the leading local heavy quark kinetic operator and μ_G^2 parameterizes the corresponding expectation value of the chromomagnetic operator. A more extensive discussion of the theoretical treatment of inclusive semileptonic decays is given in the next section.

Using $\mathcal{G}(1) = 1.04 \pm 0.06$, we get $|V_{cb}| = (40.2 \pm 3.6_{\rm exp} \pm 2.3_{\rm theo}) \times 10^{-3}$, consistent with the value extracted from $B \to D^\star\ell\nu$ decay, but with a larger uncertainty.

The experiments have also measured the differential decay rate distribution to extract the ratio $\mathcal{G}(w)/\mathcal{F}(w)$. The data are compatible with a universal from factor as predicted by HQET.

III. $|V_{cb}|$ determination from inclusive B semileptonic decays

Alternatively, $|V_{cb}|$ can be extracted from the inclusive semileptonic width, requiring measurements of both the B lifetimes and the semileptonic branching fraction B($B \to X_c\ell\nu$) [45,46]. In this case, quark-hadron duality bridges the gap between theoretical calculations and experimental observables [47]. The modern theoretical formulation based on the Operator Product Expansion (OPE) determines the inclusive decay amplitudes in inverse powers of $1/m_Q$ [45]. Non-perturbative corrections to the leading term, given by the spectator decay amplitude, arise only to order $1/m_b^2$. Quark-hadron duality is an important *ab initio* assumption in these calculations [47]. As M. Shifman put it [47], "It is fair to say that (short of the full solution of QCD) understanding and controlling the accuracy of the quark-hadron duality is one of the most important and challenging problem for the QCD practitioner today." In other words, as pointed out by Shifman and Buchalla [49], "duality violation parameterize our ignorance." Models can give estimates of the uncertainty induced by duality violations [48], [50]. These models need to have a clear physical interpretation and must be tested, in their key features, against experimental data [47]. The models quoted before imply different power suppression of duality violations. This issue needs to be resolved with further theoretical effort in defining clear and unambiguous quantitative tests of duality violations complemented by an experimental program to validate them.

The coefficients of the $1/m_b$ power terms are expectation values of operators that include non-perturbative physics. Relationships that are valid up to $1/m_b^2$ include four such parameters: the expectation value of the kinetic operator, corresponding to the average of the square of the heavy-quark momentum inside the hadron, the expectation value of the chromomagnetic operator, and the heavy-quark masses (m_b and m_c). The expectation value of the kinetic operator is introduced in the literature as μ_π^2 [45,46] or $-\lambda_1$ [51,52], and the expectation value of the chromomagnetic operator as μ_G^2 [45,46], or $3\lambda_2$ [51,52]. The two notations reflect a difference in the approach used to handle the energy scale μ used to separate long-distance from short-distance physics. HQET is most commonly renormalized in a mass-independent scheme, thus making the quark masses the pole masses of the underlying theory (QCD). The second group of authors prefer the definition of the non-perturbative operators using a mass scale $\mu \approx 1$ GeV.

The semileptonic width expression in Ref. 53 has been used to extract $|V_{cb}|$ from the semileptonic branching fraction measured by CLEO, and to measure the heavy-quark expansion (HQE) parameters $\overline{\Lambda}$ and λ_1, as discussed below. The most recent version of the alternative formulation can be found in Ref. 9.

The quark masses are related to the corresponding meson masses through [8]:

$$m_b = \overline{M}_B - \overline{\Lambda} + \frac{\lambda_1}{2\overline{M}_B}, \qquad (5)$$

where $\overline{M}_B$ is the spin averaged $B - B^\star$ mass ($\overline{M}_B = 5.3134$ GeV/c^2). A similar equation relates m_c and $\overline{M}_D$. The parameter $\overline{\Lambda}$ represents the energy of the light quark and gluons. From the equations relating m_b and m_c to the corresponding spin-averaged meson masses, experimentalists usually derive the constraint on m_c to be used in the theoretical formulae. It has been pointed out [9] that it may be opportune to replace this constraint with an independent experimental determination of m_c.

HQE and moments in semileptonic decays:

Experimental determinations of the HQE parameters are important in several respects. In particular, redundant determinations of these parameters may uncover inconsistencies, or point to violation of some important assumptions inherent in these calculations. The parameter λ_2 can be extracted from

the $B^\star - B$ mass splitting, whereas the other parameters need more elaborate measurements.

The CLEO collaboration determines the parameter $\overline{\Lambda}$ from the first moment of the γ energy in the decay $b \to s\gamma$, which gives the average energy of the γ emitted in this transition. Using the formalism of Ref. 53, they obtain $\overline{\Lambda} = 0.35 \pm 0.07 \pm 0.10$ GeV [54].

The parameter λ_1 can be determined from of the first moment of the mass M_X of the hadronic system recoiling against the $\ell - \overline{\nu}$ pair. The relationship between the first moment of $M_1 \equiv < M_X^2 - M_D^2 >$ and the parameters $\overline{\Lambda}$ and λ_1 is given in Ref. 55.

The measured value for $< M_X^2 - M_D^2 >$ [55] is 0.251 ± 0.066 GeV^2. This constraint, combined with the measurement of the mean photon energy in $b \to s\gamma$, implies a value of $\lambda_1 = -0.24 \pm 0.11$ GeV^2, to order $1/M_B^3$ and $\beta_0 \alpha_s^2$ in ($\overline{\rm MS}$).

The shape of the lepton spectrum provides further constraints on OPE. Moments of the lepton momentum with a cut $p_\ell^{CM} \geq 1.5$ GeV/c have been measured by the CLEO collaboration [62]. The two approaches give consistent results, although the technique used to extract the OPE parameters has still relatively large uncertainties associated with the $1/m_b^3$ form factors. The sensitivity to $1/m_b^3$ corrections depends upon which moments are considered. Bauer and Trott [61] have performed an extensive study of the sensitivity of lepton energy moments to non-perturbative effects. In particular, they have proposed "duality moments," very insensitive to neglected higher order terms. The comparison between the CLEO measurement of these moments [62] and the predicted values shows a very impressive agreement:

$$D_3 \equiv \frac{\int_{1.6\,\mathrm{GeV}} E_\ell^{0.7} \frac{d\Gamma}{dE_\ell} dE_\ell}{\int_{1.5\,\mathrm{GeV}} E_\ell^{1.5} \frac{d\Gamma}{dE_\ell} dE_\ell} = \begin{cases} 0.5190 \pm 0.0007 & \text{(T)} \\ 0.5193 \pm 0.0008 & \text{(E)} \end{cases}$$

$$D_4 \equiv \frac{\int_{1.6\,\mathrm{GeV}} E_\ell^{2.3} \frac{d\Gamma}{dE_\ell} dE_\ell}{\int_{1.5\,\mathrm{GeV}} E_\ell^{2.9} \frac{d\Gamma}{dE_\ell} dE_\ell} = \begin{cases} 0.6034 \pm 0.0008 & \text{(T)} \\ 0.6036 \pm 0.0006 & \text{(E)} \end{cases} \qquad (6)$$

(where "T" and "E" denote theory and experiment, respectively).

More recently, both CLEO and BaBar explored the moments of the hadronic mass M_X^2 with lower lepton momentum cuts. In order to identify the desired semileptonic decay from background processes including cascade decays, continuum leptons and fake leptons, CLEO performs a fit for the contributions of signal and backgrounds to the full three-dimensional differential decay rate distribution as a function of the reconstructed quantities q^2, M_X^2, $\cos\theta_{W\ell}$. The signal includes the components $B \to D\ell\overline{\nu}$, $B \to D^\star\ell\overline{\nu}$, $B \to D^{\star\star}\ell\overline{\nu}$, $B \to X_c\ell\overline{\nu}$ non-resonant, and $B \to X_u\ell\overline{\nu}$. The backgrounds considered are: secondary leptons, continuum leptons and fake leptons. BaBar uses a sample where the hadronic decay of one B is fully reconstructed and the charged lepton from the other B is identified. In this case the main sources of systematic errors are the uncertainties related to the detector modelling and reconstruction.

Figure 2 shows the extracted $< M_X^2 - \overline{M}_D^2 >$ moments as a function of the minimum lepton momentum cut from these two measurements, as well as the original measurement with $p_\ell \geq 1.5$ GeV/c. The results are compared with theory bands that reflect experimental errors, $1/m_b^3$ correction uncertainties and uncertainties in the higher order QCD radiative corrections [56]. The CLEO and BaBar results are consistent and show an improved agreement with theoretical predictions with respect to earlier preliminary results [57]. Moments of the M_X distribution without an explicit lepton momentum cut have been extracted from preliminary DELPHI data [58] and give consistent results.

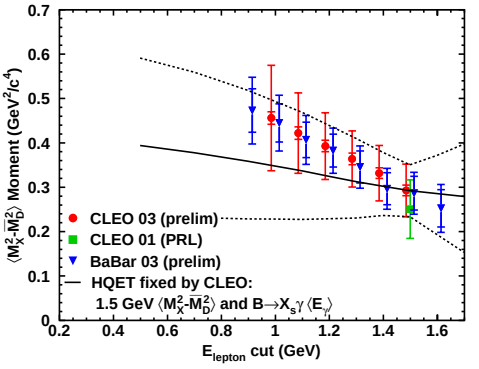

Figure 2: The results of the recent CLEO analysis [59] compared to previous measurements [55,60] and the HQET prediction. The theory bands shown in the figure reflect the variation of the experimental errors on the two constraints, the variation of the third-order HQET parameters by the scale $(0.5\ \mathrm{GeV})^3$, and variation of the size of the higher order QCD radiative corrections [56]. See full-color version on color pages at end of book.

Experimental determination of the semileptonic branching fraction:

The value of B($B \to X_c\ell\nu$) has been measured both at the $\Upsilon(4S)$ and LEP.

Experiments taking data at the Υ(4S) center-of-mass energy determine the inclusive semileptonic branching fraction through a lepton tagged sample. In this approach, a di-lepton sample is studied, and the charge correlation between the two leptons is used to disentangle leptons coming from the direct decay $B \to X_c\ell\nu$ and the dominant background at low lepton momenta, the cascade decay $B \to X_c \to X_s\ell\nu$. This method was pioneered by the ARGUS collaboration [63] to measure the electron spectrum from $B \to X_c\ell\nu$ down to 0.6 GeV/c. Thus,

it reduces the model dependence of the extracted semileptonic branching fraction very substantially. Experimental data are summarized in Table 3. The systematic error is dominated by experimental uncertainties: lepton identification efficiency, fake rate determination, and tracking efficiencies contribute to 3% of this overall error. The remaining error is a sum of several small corrections associated with the uncertainty in the mixing parameter, and additional background estimates [64]. BaBar [65] and Belle [66] have studied the inclusive electron spectrum with the same technique.

Table 3: B($b \to \ell$) measurement from experiments at $\Upsilon(4S)$ center-of-mass energy and their average. The errors quoted reflect statistical, and systematic uncertainties. These measurements are largely model independent.

Experiment	B($b \to \ell\nu$)%
ARGUS	$9.75 \pm 0.50 \pm 0.39$
CLEO	$10.49 \pm 0.17 \pm 0.43$
Belle	$10.96 \pm 0.12 \pm 0.50$
BaBar	$10.91 \pm 0.18 \pm 0.29$
Υ(4S) Average	10.73 ± 0.28

Combining $\Upsilon(4S)$ results [1], we obtain: B($b \to X\ell\nu$) = (10.73±0.28)%. Upon subtracting B($b \to u\ell\nu$) = (0.17±0.05)%, we get: B($b \to X_c\ell\nu$) = (10.56 ± 0.28)%. Using τ_{B^+}, τ_{B^0} [1], and the ratio between charged and neutral B pair production $f_{+-}/f_{00} = 1.044 \pm 0.05$ [21], we obtain the semileptonic width $\Gamma(b \to X_c\ell\nu) = (0.434 \pm 0.011 \pm 0.003) \times 10^{-10}$ MeV, where the second error includes the uncertainties from B($b \to u\ell\nu$), and the model dependence. A common value for the ratio f_{+-}/f_{00} between B^+B^- and $B^0\overline{B}^0$ final states produced at the $\Upsilon(4S)$ is used here. This parameter is very sensitive to the precise value of the center-of-mass energy and beam energy spread [70] and thus as more precise data become available, it is important to check that it is appropriate to average f_{+-}/f_{00} at different machines.

At LEP, B^0, B^-, B_s, and b baryons are produced, so the measured inclusive semileptonic branching ratio is an average over the different hadron species. Assuming that the semileptonic widths of all b hadrons are equal, the following relation holds:

$$\begin{aligned}\mathrm{B}(b \to X_c l\nu)_{\mathrm{LEP}} = & \\ & f_{B^0}\frac{\Gamma(B^0 \to X_c l\nu)}{\Gamma(B^0)} + f_{B^-}\frac{\Gamma(B^- \to X_c l\nu)}{\Gamma(B^-)} \\ & + f_{B_s}\frac{\Gamma(B_s \to X_c l\nu)}{\Gamma(B_s)} + f_{\Lambda_b}\frac{\Gamma(\Lambda_b \to X_c l\nu)}{\Gamma(\Lambda_b)} \\ & = \Gamma(B \to X_c\ell\nu)\tau_b \ , \end{aligned} \quad (7)$$

where τ_b is the average b-hadron lifetime. Taking into account the present precision of LEP measurements of b-baryon semileptonic branching ratios and lifetimes, the estimate uncertainty for a possible difference for the width of b baryons is 0.13%. The average LEP value for B($b \to X\ell\nu$) = (10.59 ± 0.30)% is taken from a fit [71], which combines the semileptonic branching ratios, the B^0–$\overline{B}^0$ mixing parameter $\overline{\chi}_b$, and $R_b = \Gamma(Z \to b\bar{b})/\Gamma(Z \to \mathrm{had})$. Ref. 72 shows that the main contribution to the model uncertainty is the composition of the semileptonic width, including the narrow, wide and non-resonant D^{**} states. B_s and b baryons are about 20% of the total signal, and their contribution to the uncertainty of the spectrum is small. In this average, we use the modelling error quoted by Ref. 72, rather than the error from the combined fit, as the ALEPH procedure is based on more recent information. The dominant errors in the combined branching fraction are the modelling of semileptonic decays (2.6%) and the detector related items (1.3%).

Subtracting B($b \to u\ell\nu$) from the LEP semileptonic branching fraction, we get: B($b \to X_c\ell\nu$) = (10.52±0.32)%, and using τ_b [1]: $\Gamma(b \to X_c\ell\nu) = (0.439 \pm 0.010 \pm 0.011) \times 10^{-10}$ MeV, where the systematic error 0.011×10^{-10}MeV reflects the B($b \to u\ell\nu$) uncertainty and the model dependence.

Combining the LEP and the $\Upsilon(4S)$ semileptonic widths, we get: $\Gamma(b \to X_c\ell\nu) = (0.44 \pm 0.01) \times 10^{-10}$ MeV, which is used in the formula of Ref. 55 to get:

$$|V_{cb}|_{\mathrm{incl}} = (41.0 \pm 0.5_{\mathrm{exp}} \pm 0.5_{\lambda_1,\overline{\Lambda}} \pm 0.8_{\mathrm{theo}}) \times 10^{-3} \ , \quad (8)$$

where the first error is experimental, and the second is from the measured value of λ_1 and $\overline{\Lambda}$, assumed to be universal up to higher orders. The third error is from $1/m_b^3$ corrections and from the ambiguity in the α_s scale definition. The error on the average b-hadron lifetime is assumed to be uncorrelated with the error on the semileptonic branching ratio.

IV. Conclusions

The values of $|V_{cb}|$ obtained both from the inclusive and exclusive method agree within errors. The value of $|V_{cb}|$ obtained from the analysis of the $B \to D^*\ell\nu$ decay is:

$$|V_{cb}|_{\mathrm{exclusive}} = (42.0 \pm 1.1_{\mathrm{exp}} \pm 1.9_{\mathrm{theo}}) \times 10^{-3} \ , \quad (9)$$

where the first error is experimental and the second error is from the $1/m_Q^2$ corrections to $\mathcal{F}(1)$. The value of $|V_{cb}|$, obtained from inclusive semileptonic branching fractions is:

$$|V_{cb}|_{\mathrm{incl}} = (41.0 \pm 0.5_{\mathrm{exp}} \pm 0.5_{\lambda_1,\overline{\Lambda}} \pm 0.8_{\mathrm{theo}}) \times 10^{-3}. \quad (10)$$

In addition, non-quantified uncertainties are associated with a possible quark-hadron duality violations when using the inclusive method. A first conservative assessment of these uncertainties may be obtained from the difference between the two values of $|V_{cb}|$ extracted from $B \to D^*\ell\overline{\nu}$ and from inclusive measurements. These data imply about 6% uncertainty for non-quantified assumptions in the inclusive determination. This result is largely affected by the quantified theoretical errors in the two determinations and thus does not give a very stringent bound.

High precision tests of lattice gauge theory calculations and more refined experimental assessments of quark-hadron duality in inclusive semileptonic decays are needed to achieve the ultimate accuracy in our knowledge of V_{cb}.

V_{cb} MEASUREMENTS

For the discussion of V_{cb} measurements, which is not repeated here, see the review on "Determination of $|V_{cb}|$."

The CKM matrix element $|V_{cb}|$ can be determined by studying the rate of the semileptonic decay $B \to D^{(*)}\ell\nu$ as a function of the recoil kinematics of $D^{(*)}$ mesons. Taking advantage of theoretical constraints on the normalization and a linear ω dependence of the form factors provided by Heavy Quark Effective Theory (HQET), the $|V_{cb}|\times F(\omega)$ and ρ^2 (a^2) can be simultaneously extracted from data, where ω is the scalar product of the two-meson four velocities, $F(1)$ is the form factor at zero recoil (ω=1) and ρ^2 is the slope, sometimes denoted as a^2. Using the theoretical input of $F(1)$, a value of $|V_{cb}|$ can be obtained.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account corrections between the measurements.

DETERMINATION OF V_{ub}

Updated December 2003 by M. Battaglia (University of California, Berkeley and LBNL) and L. Gibbons (Cornell University, Ithaca) .

The precise determination of the magnitude of V_{ub} with a robust, well-understood uncertainty remains one of the key goals of the heavy flavor physics programs, both experimentally and theoretically. Because $|V_{ub}|$, the smallest element in the CKM mixing matrix, provides a bound on the upper vertex of one of the triangles representing the unitarity property of the CKM matrix, it plays a crucial role in the examination of the unitarity constraints and the fundamental questions on which the constraints can bear (see the minireviews on the CKM matrix [1] and on CP violation [2] for details). Investigation of these issues require measurements that are precise and that have well-understood uncertainties.

The charmless semi-leptonic (s.l.) decay channel $b \to u\ell\overline{\nu}$ provides the cleanest path for the determination of $|V_{ub}|$. However, the theory for the heavy-to-light $b \to u$ transition cannot be as well constrained as that for the heavy-to-heavy $b \to c$ transition used in the determination of $|V_{cb}|$ (see the $|V_{cb}|$ minireview [3]). The extraction of $|V_{ub}|$ and the interplay between experimental measurements and their theoretical interpretation are further complicated by the large background from

$b \to c\ell\overline{\nu}$ decay, which has a rate about 60 times higher than that for charmless s.l. decay. Measurements based both on exclusive decay channels and on inclusive techniques have been, and are being, pursued.

The last several years have seen significant developments in both the theoretical framework and the experimental techniques used in the study of $b \to u\ell\overline{\nu}$. The inclusive theory has progressed significantly in categorization of the corrections to the base theory still needed, in their relative importance in different regions of phase space, and in the determination of some of them. Recent work on exclusive processes bolsters confidence in the current uncertainties for the form factor calculations needed to extract $|V_{ub}|$. Experimentally, we have new inclusive and exclusive measurements that minimize dependence on detailed modeling of the signal process to separate signal from the $b \to c\ell\overline{\nu}$ background, have well-defined sensitivities in particular regions of phase space and have improved signal-to-background ratios. These improvements provide us with a first opportunity to develop a method for a robust determination of $|V_{ub}|$ with complete error estimates, including constraints on hitherto unquantified contributions. We review the current determinations of $|V_{ub}|$, focusing primarily on these recent developments. An average of the inclusive information from all regions of phase space remains, unfortunately, beyond our reach because of the potentially sizable corrections for which we lack estimates. Rather, we combine the inclusive results to obtain a central value and, in particular, a more complete evaluation of the uncertainty than has been possible in the past.

Inclusive measurements of $b \to u\ell\overline{\nu}$:

Theoretically, issues regarding the calculation of the total semileptonic partial width $\Gamma(B \to X_u\ell\nu)$ via the operator product expansion (OPE) are well-understood [4–9]. The OPE is both a nonperturbative power series in $1/m_b$ and a perturbative expansion in α_s. At order $1/m_b^2$, it predicts

$$\Gamma(B \to X_u\ell\nu) = \frac{G_F^2|V_{ub}|^2}{192\pi^3}\, m_b^5 \times \left[1 - \frac{9\lambda_2 - \lambda_1}{2m_b^2} + \ldots - \mathcal{O}(\frac{\alpha_s}{\pi})\right] , \quad (1)$$

where λ_2 parameterizes the hyperfine interaction between the heavy quark and the light degrees of freedom and λ_1 is related to the Fermi momentum of the heavy quark. The perturbative corrections are known to order α_s^2 [10]. The OPE is alternatively expressed in terms of the nonperturbative parameters μ_π^2 and μ_G^2, which are closely related to λ_1 and λ_2, respectively, but differ significantly in their infrared treatment. Within the OPE, the importance of a proper field theoretic treatment of the parameters is paramount both for the total rate and for the restricted phase space studies discussed below. The treatment of the quark mass and its associated uncertainties are particularly important given the strong mass dependance of the width. Such considerations have led to useful definitions like the kinematic mass, which are discussed in detail in Ref. 11 and Ref. 12.

The error induced by uncertainties in the nonperturbative parameters $\lambda_{1,2}$ is relatively small, and an evaluation [13] by the LEP VUB working group yielded

$$|V_{ub}| = 0.00445 \left(\frac{\mathrm{B}(b \to u\ell\overline{\nu})}{0.002}\frac{1.55\mathrm{ps}}{\tau_b}\right)^{1/2} \times (1 \pm 0.020_{\mathrm{OPE}} \pm 0.052_{m_b}) \ . \quad (2)$$

The quoted uncertainty is dominated by the uncertainty in the b quark mass, for which $m_b^{1S}(1\ \mathrm{GeV}) = 4.58 \pm 0.09$ GeV was assumed. The value and uncertainty are in good agreement with a recent survey [14]. No weak annihilation uncertainties (discussed below) are included in the quoted OPE error. Use of the quark-level OPE for prediction of moments of the true inclusive spectra has generated concern regarding potential violation of the underlying assumption of global quark-hadron duality. This concern has been confronted by theoretical wisdom [15] supporting global duality for the inclusive $b \to u\ell\overline{\nu}$ transition, and new data both support this assumption and allow placement of quantitative limits on the violation. In particular, the exclusive and inclusive extractions of $|V_{cb}|$ agree to $(0.8 \pm 1.6) \times 10^{-3}$ [3]. Taking the uncertainty as an upper bound on the global duality violation for $|V_{ub}|$ shows that it should not exceed $\simeq$4%. Using this as bound as an uncertainty estimate for duality effects in the partial width prediction brings the total uncertainty on $|V_{ub}|$ to 6.8%. The agreement of the OPE parameters extracted using moments of different distributions in s.l. decays further supports the small scale for duality violation effects.

While theoretically the total inclusive rate would allow determination of $|V_{ub}|$ to better than 10%, experimentally the much more copious $b \to c\ell\overline{\nu}$ process makes a measurement over the full phase space unrealizable. To overcome this background, inclusive $b \to u\ell\overline{\nu}$ measurements utilize restricted regions of phase space in which the $b \to c\ell\overline{\nu}$ process is kinematically highly suppressed. The background is forbidden in the regions of large charged lepton energy $E_\ell > (M_B^2 - M_D^2)/(2M_B)$ (the endpoint), low hadronic mass $M_X < M_D$ and large dilepton mass $q^2 > (M_B - M_D)^2$. Extraction of $|V_{ub}|$ from such a measurement requires knowledge of the fraction of the total $b \to u\ell\overline{\nu}$ rate that lies within the utilized region of phase space, which complicates the theoretical issues and uncertainty considerably. Ref. 16 and Ref. 17 discuss the issues in detail.

CLEO [18], BaBar [19], and Belle [20] have all presented recent measurements of the $b \to u\ell\overline{\nu}$ rate near the endpoint. The results, which are for integrated ranges in the $\Upsilon(4S)$ rest frame, are summarized in Table 1. Experimentally, these measurements must contend with a large background from continuum e^+e^- annihilation processes. Suppression of these backgrounds introduces significant efficiency variation with the q^2 of the decay, which introduces model dependence. Greater awareness of this issue has resulted in more sophisticated suppression methods in these recent measurements and thus in over a factor of three reduction in the model dependence of the measured rates relative to earlier measurements [21, 22]. Future measurements, either using fully-reconstructed B-tag samples

that would remove the problem or a modest q^2 binning, would essentially eliminate the remaining model dependence.

Table 1: Partial branching fractions for $b \to u\ell\overline{\nu}$ within the charged lepton momentum range ($\Upsilon(4S)$ frame) from 2.6 GeV/c down to the indicated minimum. The estimated fraction f_E of the total $b \to u\ell\overline{\nu}$ rate expected to lie in that range is also given. The dagger (†) indicates the quantity that received the QED radiative correction appropriate to the indicated mix of electrons and muons, which has not always been treated self-consistently in the literature.

$p_\ell^{\min}$ (GeV/c)	$\Delta\mathcal{B}_u(p)$ (10^{-4})	f_E	
2.0	$4.22 \pm 0.33 \pm 1.78$	$\dagger 0.266 \pm 0.041 \pm 0.024$	CLEO (e,μ)
2.1	$3.28 \pm 0.23 \pm 0.73$	$\dagger 0.198 \pm 0.035 \pm 0.020$	CLEO (e,μ)
2.2	$2.30 \pm 0.15 \pm 0.35$	$\dagger 0.130 \pm 0.024 \pm 0.015$	CLEO (e,μ)

	$\dagger 1.52 \pm 0.14 \pm 0.14$	$0.078 \pm 0.015 \pm 0.009$	BaBar (e)
	$1.19 \pm 0.11 \pm 0.10$	$\dagger 0.072 \pm 0.014 \pm 0.008$	Belle (e)
2.4	$0.64 \pm 0.07 \pm 0.05$	$\dagger 0.037 \pm 0.007 \pm 0.003$	CLEO (e,μ)

BaBar [23] and Belle [24] have presented new analyses of the low M_X region [25–28]. They also utilize a moderate (only $\sim 10\%$ loss) $p_\ell > 1.0$ GeV/c requirement. This technique was pioneered by Delphi at LEP [29], but the achievable resolution and signal-to-background ratio were lower compared to those obtained at the B factories. Because of experimental resolution on M_X, the $b \to c\ell\overline{\nu}$ background smears below its theoretical lower limit of $M_X = M_D$, so experiments must impose more stringent M_X requirements which are theoretically more problematic. The BaBar and Belle analyses are based on "B-tag" samples of fully reconstructed hadronic decays and $D^{(*)}\ell\nu$ decays, respectively. In both cases, M_X is calculated directly from the particles remaining after removal of tag and lepton contributions. The BaBar analysis, in particular, reveals a beautiful $b \to u\ell\overline{\nu}$ signal with an unsurpassed signal to background ratio of about 2:1 in the region $M_X < 1.55$ GeV/c, which rivals that of current exclusive analyses. This analysis demonstrates the anticipated power of a large fully reconstructed sample, both in the signal to background levels and in the excellent resolution that can be achieved. The efficiency versus M_X appears reasonably uniform, and the signal yield fitting procedure minimizes the dependence of the extracted rate on the modeling of the detailed $b \to u\ell\overline{\nu}$ dynamics. Both allow for improved determination of $|V_{ub}|$ as theory advances.

Determination of the fraction of the $b \to u\ell\overline{\nu}$ rate in the p_ℓ endpoint or the low M_X region requires resummation of the OPE to all orders in $E_X\Lambda_{\rm QCD}/M_X^2$ [30–34]. The resummation results, at leading-twist order, in a nonperturbative shape function $f(k_+)$, where $k_+ = k^0 + k_\parallel$ and $k^\mu = p_b^\mu - m_b v^\mu$ is the residual b quark momentum after the "mechanical" portion of momentum is subtracted off. Spatial components $k_\parallel$ and $k_\perp$ are defined relative to the $m_b v^\mu - q^\mu$ (roughly the recoiling u quark) direction. At this order, effects such as the "jiggling" of $k_\perp$ are ignored and the differential partial width is given by the convolution of the shape function with the parton level differential distribution. Because the shape function depends only on parameters of the B meson, this leading order description holds for any B decay to a light quark. It holds, in particular, for $B \to s\gamma$, which can provides an estimation of $f(k_+)$ via the shape of the photon energy (E_γ) spectrum [31, 32]. In addition to the increased uncertainty on $|V_{ub}|$ from the m_b and b quark kinetic energy contributions that results from the restriction of phase space, higher twist contributions and unknown power corrections of order $\Lambda_{\rm QCD}/M_B$ [35, 36] also contribute to the uncertainty, as will be discussed further below.

Ideally, $|V_{ub}|$ would be determined without introduction of an intermediate extracted shape function through the use of appropriately weighted spectra [32,37–41]. This would avoid introduction of an element of model dependence. For the lepton spectrum, for example, one would take

$$\left|\frac{V_{ub}}{V_{tb}V_{ts}^*}\right|^2 = \frac{3\alpha}{\pi}\,K_{\rm pert}\frac{\widehat{\Gamma}_u(E_0)}{\widehat{\Gamma}_s(E_0)} + O(\Lambda_{\rm QCD}/M_B)\ , \qquad (3)$$

where $K_{\rm pert}$ is a calculable perturbative kernel, and $\widehat{\Gamma}_u(E_0)$ and $\widehat{\Gamma}_s(E_0)$ are appropriately weighted integrals over, respectively, the lepton energy and photon energy spectra above the minimum cutoff energy E_0. Practical application of this approach awaits measurement of the lepton momentum spectrum in the B, not the $\Upsilon(4S)$, rest frame, which B-tag methods will permit in the future. Similar expressions exist for integration over the low hadronic mass region [38,41], so, in principle, current M_X analyses should be able to take such an approach. Experimental efficiency and lepton momentum cutoffs must, however, be incorporated into the integrals. To date, experiments have instead introduced intermediate shape functions of a variety of forms into the inclusive analyses, as discussed below.

A third way to isolate the charmless s.l. signal is to use a selection based on the q^2 of the leptonic system. Restriction of phase space to regions of large q^2 also restores the validity of the OPE [42,43] and suppresses shape function effects. Taking only the region kinematically forbidden to $b \to c\ell\overline{\nu}$, $q^2 > (M_B - M_D)^2$, unfortunately introduces a low mass scale [44,45] into the OPE and the $1/m^3$ uncertainties blow up to be of order $(\Lambda_{\rm QCD}/m_c)^3$. However, a combination of M_X with looser q^2 requirements can suppress both $b \to c\ell\overline{\nu}$ background experimentally and shape function effects theoretically. Furthermore, the q^2 requirement moves the parton level pole away from the experimentally feasible M_X requirement. The shape function effects, while suppressed, cannot be neglected. One drawback of the q^2 requirement is the elimination of higher energy hadronic final states, which may exacerbate duality concerns.

A recent Belle analysis [46] has been performed in this region. Belle employs a $p_\ell > 1.2$ GeV/c requirement in the $\Upsilon(4S)$ rest frame, and an "annealing" procedure to separate reconstructed particles into signal and "other B" halves. They

then examine the integrated rate in the region $M_X < 1.7$ GeV and $q^2 > 8$ GeV^2 to extract $|V_{ub}|$, which again has the desired effect of minimizing dependence of the analysis on detailed $b \to u\ell\overline{\nu}$ modeling. The signal to background ratio of the annealing technique, about 1:6 for the Belle analysis, is significantly degraded relative to that of the hadronic B-tag technique. As we mentioned in the previous review, control of background subtractions of this size requires extreme care and careful scrutiny of the associated systematic issues. Belle finds the rate $\Delta\mathcal{B}$ in that region of phase space to be

$$\Delta\mathcal{B} = (7.37 \pm 0.89_{\rm stat} \pm 1.12_{\rm sys} \pm 0.55_{c\ell\nu} \pm 0.24_{u\ell\nu}) \times 10^{-4} \ . \quad (4)$$

An analysis of this restricted region of phase space, for which the shape function influence is significantly reduced [42], with the significantly cleaner B tag technique should be a priority for both B experiments.

Each analysis discussed here has relied on an intermediate shape function to evaluate the fraction of the inclusive rate that lies in its restricted region of phase space. The endpoint analyses have used rate fractions [18] based on intermediate shape functions derived from the CLEO $b \to s\gamma$ photon spectrum. Several two-parameter ansaetze [47,48], $F[\Lambda^{SF}, \lambda_1^{SF}]$, were implemented as the form of the shape function. These parameters are related to the HQET parameters of similar name, and play a similar role in evaluation of the rates. At this time, however, we do not know the precise relationship between the shape function parameters, or the moments of the shape function, and the HQET nonperturbative parameters $\overline{\Lambda}$ and λ_1 [49,50]. The fact that Λ^{SF} and λ_1^{SF} depend on the functional ansatz while the HQET parameters depend on the renormalization scheme underscores the current ambiguity.

With the limited E_γ statistics available, there exists a strong correlation between the two parameters because of the interplay between the effective b quark mass (controlled by Λ^{SF}) and the effective b quark kinetic energy (controlled by λ_1^{SF}) in determining the *mean* of the E_γ spectrum. No external constraints that could break the correlation, such as $m_b^{(1S)}$ or measured $b \to c\ell\overline{\nu}$ moments, have been input into the $b \to s\gamma$ fits because of their unknown relationship to the shape function parameters. The resulting effective m_b mass range contributing to the uncertainties ($\pm$200 MeV) is therefore much larger than the current m_b uncertainty. Given the current independence of the shape function and m_b determinations and the broad effective m_b range sampled in the shape function, we do not consider it necessary to treat the E_γ-derived phase space fractions and the partial width (Eq. (2)) as positively correlated [46]. As the data statistics increase, it will become possible to constrain the shape function parameters directly from distributions in $b \to u\ell\overline{\nu}$, such as the M_X spectrum, thus removing the uncertainties introduced from their derivation from another class of decays. Furthermore, once the renormalization behaviour of the shape function and the relationship of its moments to the HQET parameters becomes known, the powerful constraints from the kinematic mass of the b quark and from moments information in the $b \to c\ell\nu$ system can be incorporated into a shape function derivation based either on $b \to s\gamma$ or $b \to u\ell\overline{\nu}$.

Two alternate approaches to the shape function evaluation have been taken in experimental studies so far. In their low-M_X analysis [23], BaBar has evaluated the phase space fraction using the same $f(k_+)$ parameterizations noted above, but has substituted HQET parameters derived from studies of spectral moments of the $b \to s\gamma$ and $b \to c\ell\overline{\nu}$ processes. The Belle M_X-q^2 analysis [46](discussed below) uses the calculation of Bauer *et al.* [42] based on a form with a single parameter $a = \Lambda^{SF}/\lambda_1^{SF}$, which was estimated from the $m_b^{(1S)}$ mass and from typical estimates for λ_1. The uncertainties in the different rate fractions in the momentum endpoint, the low M_X and the M_X-q^2 regions are strongly correlated, and the values and uncertainties are sensitive to the theoretical assumptions made. Hence, a common theoretical scheme must be chosen for meaningful comparison of the extracted values of $|V_{ub}|$. Given the *ad hoc* nature of the association of shape function parameters with the HQET parameters in the $\overline{MS}$ or the $\Upsilon(1S)$ mass scheme [7], and the difficulty in evaluating the uncertainty in such an association, we have chosen to extract $|V_{ub}|$ from all of the measurements discussed using the $b \to s\gamma$-derived shape function.

Table 2: Summary of inclusive $|V_{ub}|$ measurements. The last five measurements are incorporated into the analysis presented below. The errors in the first group are the experimental and theoretical uncertainties. The errors in the second group are from the statistical, experimental systematic, E_γ-based rate fraction, and $\Gamma_{\rm tot}$ uncertainties. The two groups are *not* directly comparable as they have not been evaluated with identical theoretical inputs.

The full set of inclusive $|V_{ub}|$ results is summarized in Table 2, which is an updated version of the Heavy Flavors Averaging Group summary [51]. All endpoint results have QED radiative corrections applied correctly. The listed uncertainties do not include contributions for potentially large theoretical corrections that have been categorized but remain incalculable (see below). The last five results in the table, which we will use

below, have been updated to a common framework based on the CLEO E_γ-derived shape function. The rate fractions [52] for the BaBar M_X analysis (f_M) and the Belle $M_X - q^2$ analysis f_{qM} are $f_M = 0.55 \pm 0.14$ and $f_{qM} = 0.33 \pm 0.07$. The central values for these and for the endpoint fractions (Table 1) correspond to an exponential shape function ansatz [48] and $(\lambda_1^{SF}, \overline{\Lambda}^{SF}) = (-0.342, 0.545)$, with small corrections related to background subtractions in the $b \to s\gamma$ spectrum. The errors are dominated by the statistical uncertainty in the $f(k_+)$ fit to the E_γ spectrum, but include contributions from experimental systematics, α_s uncertainties and modeling. Incorporation of results beyond those used here will require significant input from the experimental analyses, and is left to the HFAG.

Combining inclusive information:

Evaluation of the total uncertainty on $|V_{ub}|$ remains problematic because of a variety of theoretical complications. A recent review [16] discusses these issues in detail. There are three main contributions. The first arises from subleading (higher twist) contributions to the shape function resummation [57–61]. These involve incorporation of effects such as the variation of $k_\perp$, and are not universal for all B decay processes. Hence with the use of $b \to s\gamma$ to obtain a shape function, there are two contributions, one from subleading contributions to the use of a shape function in $b \to u\ell\overline{\nu}$ process itself, and the second from the different corrections in $b \to s\gamma$ from which the shape function is obtained. These contributions are potentially large, since they are of order $\Lambda_{\rm QCD}/m_b$. Indeed, a partial estimate of these effects [59] for the momentum endpoint region finds corrections that are similar in size to the total uncertainties of those analyses. Recent work indicates that the subleading contributions for $u\ell\nu$ and $s\gamma$ may partially cancel in the low M_X and the low M_X-high q^2 regions [61].

The second contribution, from "weak annihilation" processes, is formally of order $(\Lambda_{\rm QCD}/m_b)^3$ but receives a large multiplicative enhancement of $16\pi^2$ [62,63]. The contribution, which requires factorization violation to be nonzero, is expected to be localized near $q^2 \sim m_b^2$, and this localization can result in a further enhancement of the effect on $|V_{ub}|$. For the endpoint region, which sees about 10% of the total rate, an effect on the total rate of 2-3% (corresponding to factorization violation of about 10%), produces an effect on the measured rate of 20-30%.

Finally, there are unknown contributions from potential violation of local quark hadron duality. The true differential distribution cannot be predicted via the OPE—the resonant substructure is not described. However, spectra integrated over a sufficiently broad range should be better described.

The problems just outlined present a challenge to the averaging of the various inclusive results. Results with a potentially large bias might be included with neither a correction nor an appropriate uncertainty due to these effects. The resulting $|V_{ub}|$ determination would be potentially biased and the attached uncertainty unreliable. This motivated us not to provide an average result in the first edition of this review two years ago.

As an alternative, we here choose measurements in the region of phase space that appears to have the best compromise of the affects discussed to obtain an estimate of $|V_{ub}|$. Measurements from the other regions of phase space, which have increased sensitivity to one or more of the corrections, then provide limits on the uncertainties from these effects and thereby allow as complete as possible an estimation of the theoretical uncertainty, as first proposed by Ref. 52. At this time, the low M_X, high q^2 region appears to be the best motivated choice. It has reduced (though by no means negligible) corrections from the shape function and thus also from the subleading contributions to the shape function. Yet it integrates over a sufficient fraction of the spectrum to dilute weak annihilation contributions and concerns on local quark hadron duality.

While this choice is at present subjective, it offers the advantage of a reduction of the shape function influence coupled with the ability to bound the remaining theoretical uncertainties. In the opinion of the reviewers, this is a reasonable tradeoff for the statistical loss relative to the low M_X region. We expect that each experiment will perform an improved combination of information from the different regions of phase space where the experimental and theoretical correlations can be made manifest more straightforwardly.

We further stress that we view all three regions as equally crucial in this combination of information, as a more complete evaluation of the inclusive uncertainty than has previously existed is necessary for proper use of the inclusive results. The choice of the phase space region should not be misconstrued as a preference of experimental technique. Indeed, we look forward to a similar (or improved) analysis when a sample of clean results based on fully tagged B samples have been obtained for all regions of phase space.

At present only Belle [46] has contributed a result for this region of phase space, so for now we take this result as the "central value":

$$|V_{ub}|/10^{-3} = 4.63 \pm 0.28_{\rm stat} \pm 0.39_{\rm sys} \pm 0.48_{\rm f_{qM}} \pm 0.32_{\Gamma \rm thy} \pm \sigma_{\rm WA} \pm \sigma_{\rm SSF} \pm \sigma_{\rm LQD} \ . \quad (5)$$

Additional measurements by the B factories of the rate in this region of phase space will soon improve the experimental uncertainties.

We must determine the last three uncertainties for weak annihilation (WA), subleading shape function corrections (SSF) and local quark hadron duality (LQD). The measurements from other regions of phase space are crucial for this task.

We assume that the WA contribution is largely contained within each of the $p_\ell > 2.2$ GeV/c, the $M_X < 1.55$ GeV and the combined $M_X < 1.7$ GeV, $q^2 > 8$ GeV^2 regions. The contribution will be most diluted in the low M_X region, with the rate fraction $f_M = 0.55 \pm 0.14$, and most concentrated in the endpoint region, with the rate fraction $f_e = 0.14 \pm 0.03$ (without radiative corrections). It is simple to show that for a neglected WA contribution, a comparison of $|V_{ub}|$ from these

two regions would predict the bias in the M_X, q^2 region (with rate fraction $f_{qM} = 0.33 \pm 0.07$) to be

$$[(1 - f_{qM})/f_{qM}][f_e f_M/(f_M - f_e)] \approx 0.39 \qquad (6)$$

of the observed difference. Comparison of the endpoint result from CLEO and the low M_X result from BaBar, taking into consideration the almost total correlation in the shape function and Γ_{tot} uncertainties, yields $\Delta|V_{ub}|/10^{-3} = 0.69 \pm 0.53$. There is not sufficient sensitivity to draw conclusions regarding the presence of a WA component, but we can place a bound. We take the larger of the error and central value and scale according to Eq. (6) to obtain

$$\sigma_{\rm WA} \approx 0.27 \ . \qquad (7)$$

To estimate the uncertainty from the subleading corrections to the shape function, we assume that subleading corrections will scale like the fractional change in the predicted rate ($\Delta\Gamma/\Gamma$) with and without convolution of the parton-level expression with the shape function. As the base comparison, we take the low M_X region, with $(\Delta\Gamma/\Gamma)_M = 0.15$, and compare to the combined M_X, q^2 region, with $(\Delta\Gamma/\Gamma)_{qM} = -0.075$). The shifts again depend on the shape function modeling, and the quoted values correspond to the $f(k_+)$ from the best fit to the CLEO E_γ spectrum . The theory uncertainties are again correlated, and we find $\Delta|V_{ub}|/10^{-3} = 0.16 \pm 0.63$. Scaling the uncertainty of the comparison by $|(\Delta\Gamma/\Gamma)_{qM}/(\Delta\Gamma/\Gamma)_M| = 0.49$, we have

$$\sigma_{\rm SSF} \approx 0.31 \ . \qquad (8)$$

Finally, we must make an estimate of the local duality uncertainty. We assume that a potential violation will scale with the fraction of rate f in a given region as $(1 - f)/f$. This form ranges from no "local" violation for integration of the full phase space ($f = 1$), to large uncertainty for use of a very localized region of phase space ($f \to 0$). The estimate derives from comparison of the CLEO $p_\ell > 2.2$ GeV/c analysis ($f \sim 0.14 \pm 0.03$) to the average of the BaBar and Belle $p_\ell > 2.3$ GeV/c analyses ($f \sim 0.07 \pm 0.02$). The subleading correction estimates of Ref. 59 are applied to minimize potential cancelation between duality violation and subleading corrections. This yields $(|V_{ub}|^{2.3} - |V_{ub}|^{2.2} + 0.27)/10^{-3} = 0.29 \pm 0.38$, where the 0.27 is the estimate of the relative subleading correction. With our scaling assumption, we then apply a scale factor s of

$$s = \frac{(1 - f_{qM})/f_{qM}}{(1 - f_{2.3})/f_{2.3} - (1 - f_{2.2})/f_{2.2}} \approx 0.29 \qquad (9)$$

to the uncertainty in this difference estimate. Our local duality estimate therefore is

$$\sigma_{\rm LQD} \sim 0.11.$$

From this analysis, we finally obtain

$$|V_{ub}|/10^{-3} = 4.63 \pm 0.28_{\rm stat} \pm 0.39_{\rm sys} \pm 0.48_{f_{qM}} \pm 0.32_{\Gamma\rm thy} \pm 0.27_{\rm WA} \pm 0.31_{\rm SSF} \pm 0.11_{\rm LQD} \ , \qquad (10)$$

for a total theory error of 15% and total precision of 18%. Given that the uncertainties are dominated by experimental limits, addition in quadrature seems appropriate. Note that these estimates apply *only* in the combined low M_X, high q^2 region of phase space. The limits presented here can be improved both in robustness, through more sophisticated scaling estimates, and in magnitude, through additional and improved $|V_{ub}|$ measurements and through inputs from other sources. The consistency of the values of $|V_{ub}|$ extracted with different inclusive methods and the stability of the results over changes in the selected region of phase space will provide increasing confidence in the reliability of the extracted results and of their estimated uncertainties. Improvement of the $b \to s\gamma$ photon energy spectrum is key until a self-consistent extraction of the shape function from $b \to u\ell\overline{\nu}$ transition becomes available. Comparisons of the D^0 versus D_s semileptonic widths and of the rates for charged versus neutral B mesons can provide estimates of the weak annihilation contributions [63]. Finally, improved theoretical guidance concerning the scaling of the effects over phase space would allow development of a simultaneous extraction of $|V_{ub}|$ and the corrections, with all experimental information contributing directly to $|V_{ub}|$.

Exclusive measurements of $b \to u\ell\overline{\nu}$:

Reconstruction of exclusive $b \to u\ell\overline{\nu}$ channels provides powerful kinematic constraints for suppression of the $b \to c\ell\overline{\nu}$ background. For this suppression to be effective, an estimate of the four momentum of the undetected neutrino must be provided. The measurements to date have made use of detector hermeticity and the well-determined beam parameters to define a missing momentum that is used as the neutrino momentum. Signal-to-background ratios (S/B) of order two have been achieved in these channels.

To extract $|V_{ub}|$ from an exclusive channel, the form factors for that channel must be known. The form factor normalization dominates the uncertainty on $|V_{ub}|$. The q^2-dependence of the form factors, which is needed to determine the experimental efficiency, also contributes to the uncertainty, but at a much reduced level. For example, the requirement of a stiff lepton for background reduction in these analyses introduces a q^2-dependence to the efficiency. In the limit of a massless charged lepton (a reasonable limit for the electron and muon decay channels), the $B \to \pi\ell\nu$ decay depends on one form factor $f_1(q^2)$:

$$\frac{d\Gamma(B^0 \to \pi^-\ell^+\nu)}{dy\, d\cos\theta_\ell} = |V_{ub}|^2 \frac{G_F^2 p_\pi^3 M_B^2}{32\pi^3} \sin^2\theta_\ell |f_1(q^2)|^2 \ , \qquad (11)$$

where $y = q^2/M_B^2$ and θ_ℓ is the angle between the charged lepton direction in the virtual W ($\ell + \nu$) rest frame and the direction of the virtual W. For the vector meson final states ρ and ω, three form factors A_1, A_2, and V are necessary (see *e.g.* reference [64]).

Calculation of these form factors constitutes a considerable theoretical industry, with a variety of techniques now being employed. Form factors based on lattice QCD calculations [65–77] and on light cone sum rules [78–87] currently have uncertainties in the 15% to 20% range. A variety of quark model calculations

exists [88–102]. Finally, a number of other approaches [103–109], such as dispersive bounds and experimentally-constrained models based on Heavy Quark Symmetry, seek to improve the q^2 range where the form factors can be estimated, without introducing significant model dependence.

Of particular interest are the light cone sum rules (LCSR) and lattice QCD (LQCD) calculations, which minimize modeling assumptions as they are QCD-based calculations and provide a much firmer basis compared to the quark model calculations for systematic evaluation of the uncertainties. The calculations used in the current results have been summarized nicely in Ref. 11. The LCSR are expected to be valid in the region $q^2 \lesssim 16$ GeV^2. The light cone sum rules calculations use quark-hadron duality to estimate some spectral densities, and offer a "canonical" contribution to the related uncertainty of 10% with no known means of rigorously limiting that uncertainty. The theory community is currently debating the size of potential contributions to the form factors missing from the LCSR approach [110–114] that have been revealed using the newly-developed soft collinear effective theory (SCET) [115–118]. The

$B \to \rho\ell\nu$ form factors, in particular, could be appreciably overestimated, biasing $|V_{ub}|$ low. Two exclusive results will therefore be presented in this review, one based on the full set of exclusive results, and the second based only on results in the $q^2 > 16$ GeV^2 region for $B \to \rho\ell\nu$.

The LQCD calculations that can be applied to experimental $B \to X_u\ell\nu$ decay remain, to date, in the "quenched" approximation (no light quark loops in the propagators), which limits the ultimate precision to the 15% to 20% range. The q^2 range accessible to these calculations has been $q^2 \gtrsim 16$ GeV^2. Significant progress has been made towards unquenched lattice QCD calculations, and a recent comparison [119] of a range unquenched results to experiment shows much better agreement (few percent) than the corresponding quenched results. Work has begun on the unquenched form factors needed for $|V_{ub}|$, though the initial results have been limited to valence quarks closer to the strange quark mass. Nevertheless, initial results [120,121] are compatible with the 15% to 20% uncertainties used for the quenching uncertainty, lending them some validity.

The exclusive $|V_{ub}|$ results are summarized in Table 3. These include a simultaneous measurement of the $B \to \pi\ell\overline{\nu}$ and the $B \to \rho\ell\overline{\nu}$ transitions by CLEO [122], and measurement of the $B \to \rho\ell\overline{\nu}$ rate by CLEO [123] and BaBar [124]. All measurements employ the missing energy and momentum to estimate the neutrino momentum. With that technique, the major background results from $b \to c\ell\overline{\nu}$ decays in events that cannot be properly reconstructed (for example, because of additional neutrinos in the event) and hence which overestimate the neutrino energy. All measurements also employ the isospin relations

$$\Gamma(B^0 \to \pi^-\ell^+\nu) = 2\Gamma(B^+ \to \pi^0\ell^+\nu)$$

and

$$\Gamma(B^0 \to \rho^-\ell^+\nu) = 2\Gamma(B^+ \to \rho^0\ell^+\nu) \qquad (12)$$

to combine the charged and neutral decays. These relationships can be distorted by $\rho-\omega$ mixing [125], and all results discussed here allow for this possibility in their systematic evaluation.

In the combined π and ρ measurement, strict event quality requirements were made that resulted in a low efficiency, but a relatively low background to signal ratio over a fairly broad lepton momentum range. The ρ-only analyses employ looser event cleanliness requirements, resulting in a much higher efficiency. The efficiency gain comes at the price of an increased background, and the analyses are primarily sensitive to signal with lepton momenta above 2.3 GeV/c, which is near (and beyond) the kinematic endpoint for $b \to c\ell\overline{\nu}$ decays which are therefore highly suppressed.

The combined π and ρ analysis of CLEO employs relatively loose lepton selection criteria and extracts rates independently in three separate q^2 intervals. Form factor dependence of the rates is then evaluated using models and calculations that exhibit a broad variation in $d\Gamma/dq^2$, which shows that this approach has eliminated model dependence of the rates in $\pi\ell\nu$, and significantly reduced it in $\rho\ell\nu$. To further reduce modeling uncertainties, CLEO then extracts $|V_{ub}|$ using only the LQCD and LCSR QCD-based calculations restricted to their respective valid q^2 ranges, thereby eliminating modeling used for extrapolation. Averages of the CLEO results, with and without the low q^2 region for $\rho\ell\nu$ are listed in Table 3.

A more complete review of recent $B \to X_u\ell\nu$ branching fractions, including analyses too incomplete for inclusion in this $|V_{ub}|$ summary, can be found in Reference [126]. Of note is the recent evidence presented for $B \to \omega\ell\nu$ by Belle [127].

With all results resting on use of detector hermeticity, the potential for significant correlation among the dominant experimental systematics exists [126]. Results from the three measurements have been averaged here assuming full correlation in these systematics. The $\rho\ell\nu$-only results [123,124], which depend more heavily on modeling even for the LCSR and LQCD calculations, are deweighted by 5% in the average. This yields

$$|V_{ub}| = (3.27 \pm 0.13 \pm 0.19^{+0.51}_{-0.45}) \times 10^{-3} \qquad (13)$$

where the errors arise from statistical, experimental systematic and form factor uncertainties, respectively. While similar in precision to the exclusive result in the previous $|V_{ub}|$ minireview, this result relies much less heavily on modeling. Should the LCSR form factors prove to be overestimated, we also provide an average excluding any result using information for $q^2 < 16$ GeV^2 in the $\rho\ell\nu$ modes, with the result

$$|V_{ub}| = (3.26 \pm 0.19 \pm 0.15 \pm 0.04^{+0.54}_{-0.39}) \times 10^{-3}\ , \qquad (14)$$

where the errors arise from statistical, experimental systematic $\rho\ell\nu$ form factor uncertainties, and LQCD and LCSR (treated as correlated), respectively.

Table 3: Summary of all exclusive $|V_{ub}|$ measurements. For the CLEO 00 and BaBar 01 measurements, the errors arise from statistical, experimental systematic and form factor modeling uncertainties, respectively. For the CLEO 03 measurements, the errors arise from statistical, experimental systematic, $\rho\ell\nu$ form factor, and LQCD and LCSR calculation uncertainties, respectively. In the CLEO 03 averages, the LQCD and LCSR uncertainties have been treated as correlated.

mode	$\lvert V_{ub}\rvert(10^{-3})$	q^2 range	FF
CLEO 00 $\rho\ell\nu$	$3.23 \pm 0.24^{+0.23}_{-0.26} \pm 0.58$	all	model survey

CLEO 03 $\rho\ell\nu$	$3.34 \pm 0.32\ ^{+0.27}_{-0.36} \pm 0.47\ ^{+0.50}_{-0.40}$	$q^2 > 16$ GeV^2	LQCD
CLEO 03 $\rho\ell\nu$	$3.00 \pm 0.21^{+0.29}_{-0.35} \pm 0.28^{+0.49}_{-0.38}$	average	
CLEO 03 $\pi + \rho$	$3.17 \pm 0.17^{+0.16}_{-0.17} \pm 0.03^{+0.53}_{-0.39}$	average	
CLEO 03 $\pi + \rho$	$3.26 \pm 0.19 \pm 0.15 \pm 0.04^{+0.54}_{-0.39}$	average	no $\rho\ell\nu$ LCSR

The future for exclusive determinations of $|V_{ub}|$ appears promising. Unquenched lattice calculations are appearing, with very encouraging results. These calculations will eliminate the primary source of uncontrolled uncertainty in these calculations, and have already provided some validity to the quenching uncertainty estimate used in the results presented here. Simultaneously, the B factories are performing very well, and very large samples of events in which one B meson has been fully reconstructed are already being used. This will allow a more robust determination of the neutrino momentum, and should allow a significant reduction of backgrounds and experimental systematic uncertainties. The high statistics should also allow more detailed measurements of $d\Gamma/dq^2$, which have already provided a sorely-needed litmus test for the form factor calculations and reduced the form factor shape contribution to the uncertainty on $|V_{ub}|$. Should theory allow use of the full range of q^2 in the extraction of $|V_{ub}|$ [128], the B factories have already logged data sufficient for a 5% statistical determination of $|V_{ub}|$.

For both lattice and the B factories, $\pi\ell\nu$ appears to be a golden mode for future precise determination of $|V_{ub}|$. The one caveat is management of contributions from the B^* pole, but recent work [76] suggests that this problem can be successfully overcome. $B \to \eta\ell\nu$ will provide a valuable cross check. The $\rho\ell\nu$ mode will be more problematic for high precision: the broad width introduces both experimental and theoretical difficulties. Experiments must, for example, assess potential nonresonant $\pi\pi$ contributions, but only crude arguments based on isospin and quark-popping have been brought to bear to date. Theoretically, no calculation, including lattice, has dealt with the width of the ρ. When the lattice calculations become unquenched, the ρ will become unstable and the $\pi\pi$ final state must be faced by the calculations. The methodology for accommodation of high-energy two particle final states on the lattice has yet to be developed. The $\omega\ell\nu$ mode may provide a more tractable alternative to the ρ mode because of the relative narrowness of the ω resonance. Agreement between accurate $|V_{ub}|$ determinations from $\pi\ell\nu$ and from $\omega\ell\nu$ will provide added confidence in both.

Combined results:

The experimental bounds provided for the outstanding uncertainties in the inclusive $|V_{ub}|$ measurements in the low M_X, high q^2 region and theoretical work which clarifies the reliability of the LCSR and quenched LQCD form factors make possible comparison of the inclusive and exclusive determinations of $|V_{ub}|$. Results agree to better than 1.5 times the quadratic combination of the quoted uncertainties. Therefore it becomes feasible to propose an average the inclusive and exclusive results, which have comparable accuracies.

The uncertainties have been combined in quadrature, using the larger (upward) error for the exclusive numbers. The proposed average of the inclusive and exclusive results, with all the exclusive data considered, is

$$|V_{ub}| = (3.67 \pm 0.47) \times 10^{-3}\ . \qquad (15)$$

Including in the average only the exclusive analyses based on data with $q^2 > 16$ GeV^2 in the $\rho\ell\nu$ mode, the average becomes $|V_{ub}| = (3.70 \pm 0.49) \times 10^{-3}$, so exclusion of this region, if appropriate, has only a minor effect.

The procedure proposed here results in a value of $|V_{ub}|$ with a 13% uncertainty. With the experimental and theoretical progress expected over the next few years an improvement of the accuracy at the 10% level, and possibly below, appears now realizable.

V_{ub} MEASUREMENTS

For the discussion of V_{ub} measurements, which is not repeated here, see the review on "Determination of $|V_{ub}|$."

The CKM matrix element $|V_{ub}|$ can be determined by studying the rate of the charmless semileptonic decay $b \to u\ell\nu$. Measurements based on exclusive decay channels and on inclusive techniques can be found in the previous *B* Listings, which will not repeat here.

[1] u, d, s flavor averaged.

[2] These papers report E_γ in the B^* center of mass. The $m_{B^*} - m_B$ is 0.2 MeV higher. E_{cm} = 10.61–10.7 GeV. Admixture of B^0 and B^+ mesons, but not B_s.

[3] LEE-FRANZINI 90 value is for an admixture of B^0 and B^+. They measure 46.7 ± 0.4 ± 0.2 MeV for an admixture of B^0, B^+, and B_s, and use the shape of the photon line to separate the above value.

[4] HAN 85 is for E_{cm} = 10.6–11.2 GeV, giving an admixture of B^0, B^+, and B_s.

5713± 2		[4] ACCIARRI	99N	L3	$e^+e^- \to Z$

[1] AFFOLDER 01F uses the reconstructed B meson through semileptonic decay channels. The fraction of light B mesons that are produced at L=1 B^{**} states is measured to be 0.28 ± 0.06 ± 0.03.

[2] BARATE 98L uses fully reconstructed B mesons to search for B^{**} production in the $B\pi^\pm$ system. In the framework of heavy quark symmetry (HQS), they also measured the mass of B_2^* to be 5739^{+8+6}_{-11-4} MeV/c^2 and the relative production rate of $B(b \to B_2^* \to B^{(*)}\pi)/B(b \to B_{u,d}) = (31 \pm 9^{+6}_{-5})\%$.

[3] Using $m_{B\pi} - m_B$ = 424 ± 4 ± 10 MeV.

[4] ACCIARRI 99N uses inclusive reconstructed B mesons to search for B^{**} production in the $B^{(*)}\pi^\pm$ system. In the framework of HQET, they measured the mass of B_1^* and B_2^* to be 5670±10±13 MeV and 5768±5±6 with the $B(b \to B^{**}) = (32 \pm 3 \pm 6) \times 10^{-2}$. They also reported the evidence for the existence of an excited B-meson state or mixture of states in the region 5.9–6.0 GeV.

B_s^0 MEAN LIFE

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account corrections between the measurements and asymmetric lifetime errors.

[3] Uses $D_s^- \ell^+$, and $\phi\ell^+$ vertices.
[4] Measured using D_s hadron vertices.
[5] Measured using $D_s^- \ell^+$ vertices.
[6] Measured using fully reconstructed $B_s \to J/\psi(1S)\phi$ decay.
[7] ACKERSTAFF 98F use fully reconstructed $D_s^- \to \phi\pi^-$ and $D_s^- \to K^{*0}K^-$ in the inclusive B_s^0 decay.
[8] Measured using inclusive D_s vertices.
[9] Combined results from $D_s^- \ell^+$ and D_s hadron.
[10] ABE 96N uses 58 ± 12 exclusive $B_s \to J/\psi(1S)\phi$ events.
[11] Measured using $\phi\ell$ vertices.
[12] Combined result for the four ABREU 96F methods.
[13] Exclusive reconstruction of $B_s \to \psi\phi$.
[14] ABREU 94E uses the flight-distance distribution of D_s vertices, ϕ-lepton vertices, and $D_s\mu$ vertices.

B_{sL}^0 MEAN LIFE

B_{sL}^0 is a long-lived CP-even state of two B_s^0 CP eigenstates.

VALUE (10^{-12} s)	DOCUMENT ID		TECN	COMMENT
1.27±0.33±0.08	[15] BARATE	00K	ALEP	$e^+e^- \to Z$

[15] Uses $\phi\phi$ correlations from $B_s^0 \to D_s^{(*)+} D_s^{(*)-}$.

$|\Delta\Gamma_{B_s^0}|/\Gamma_{B_s^0}$

$\Gamma_{B_s^0}$ and $|\Delta\Gamma_{B_s^0}|$ are the decay rate average and difference between two B_s^0 CP eigenstates.

The second "OUR EVALUATION," < 0.54 (CL=95%), is an average of all available B_s semi-leptonic lifetime measurements with the $\Delta\Gamma_{B_s^0}/\Gamma_s$ analyses performed by the Heavy Flavor Averaging Group (HFAG) as described in our "Review on B-$\overline{B}$ Mixing" in the B^0 Section of these Listings.

The first "OUR EVALUATION," < 0.29 (CL=95%), also provided by the HFAG, including the assumption of $\Gamma_s = \frac{1}{\tau_{B_d}}$.

[16] Uses $D_s^- \ell^+$, and $\phi\ell^+$ vertices.
[17] Measured using D_s hadron vertices.
[18] Uses $\phi\phi$ correlations from $B_s^0 \to D_s^{(*)+} D_s^{(*)-}$.
[19] ABE 99D assumes $\tau_{B_s^0} = 1.55 \pm 0.05$ ps.
[20] ACCIARRI 98S assumes $\tau_{B_s^0} = 1.49 \pm 0.06$ ps and PDG 98 values of b production fraction.

B_s^0 DECAY MODES

These branching fractions all scale with $B(\overline{b} \to B_s^0)$, the LEP B_s^0 production fraction. The first four were evaluated using $B(\overline{b} \to B_s^0) = (10.7 \pm 1.4)\%$ and the rest assume $B(\overline{b} \to B_s^0) = 12\%$.

The branching fraction $B(B_s^0 \to D_s^- \ell^+ \nu_\ell \text{anything})$ is not a pure measurement since the measured product branching fraction $B(\overline{b} \to B_s^0) \times B(B_s^0 \to D_s^- \ell^+ \nu_\ell \text{anything})$ was used to determine $B(\overline{b} \to B_s^0)$, as described in the note on "Production and Decay of b-Flavored Hadrons."

For inclusive branching fractions, *e.g.*, $B \to D^\pm$ anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

	Mode	Fraction (Γ_i/Γ)		Confidence level

[a] Not a pure measurement. See note at head of B_s^0 Decay Modes.

[b] The value is for the sum of the charge states or particle/antiparticle states indicated.

B_s^0 BRANCHING RATIOS

$\Gamma(D_s^- \text{anything})/\Gamma_{\text{total}}$ Γ_1/Γ

VALUE	EVTS	DOCUMENT ID		TECN	COMMENT
0.93 $\pm$ 0.30 OUR AVERAGE					
0.81 $\pm$ 0.24 $\pm$ 0.22	90	[21] BUSKULIC	96E	ALEP	$e^+e^- \to Z$
1.56 $\pm$ 0.58 $\pm$ 0.44	147	[22] ACTON	92N	OPAL	$e^+e^- \to Z$

[21] BUSKULIC 96E separate $c\overline{c}$ and $b\overline{b}$ sources of D_s^+ mesons using a lifetime tag, subtract generic $\overline{b} \to W^+ \to D_s^+$ events, and obtain $B(\overline{b} \to B_s^0) \times B(B_s^0 \to D_s^- \text{anything}) = 0.088 \pm 0.020 \pm 0.020$ assuming $B(D_s \to \phi\pi) = (3.5 \pm 0.4) \times 10^{-2}$ and PDG 1994 values for the relative partial widths to other D_s channels. We evaluate using our current values $B(\overline{b} \to B_s^0) = 0.107 \pm 0.014$ and $B(D_s \to \phi\pi) = 0.036 \pm 0.009$. Our first error is their experiment's and our second error is that due to $B(\overline{b} \to B_s^0)$ and $B(D_s \to \phi\pi)$.

[22] ACTON 92N assume that excess of 147 ± 48 D_s^0 events over that expected from B^0, B^+, and $c\overline{c}$ is all from B_s^0 decay. The product branching fraction is measured to be $B(\overline{b} \to B_s^0) B(B_s^0 \to D_s^- \text{anything}) \times B(D_s^- \to \phi\pi^-) = (5.9 \pm 1.9 \pm 1.1) \times 10^{-3}$. We evaluate using our current values $B(\overline{b} \to B_s^0) = 0.107 \pm 0.014$ and $B(D_s \to \phi\pi) = 0.036 \pm 0.009$. Our first error is their experiment's and our second error is that due to $B(\overline{b} \to B_s^0)$ and $B(D_s \to \phi\pi)$.

$\Gamma(D_s^- \ell^+ \nu_\ell \text{anything})/\Gamma_{\text{total}}$ Γ_2/Γ

The values and averages in this section serve only to show what values result if one assumes our $B(\overline{b} \to B_s^0)$. They cannot be thought of as measurements since the underlying product branching fractions were also used to determine $B(\overline{b} \to B_s^0)$ as described in the note on "Production and Decay of b-Flavored Hadrons."

VALUE	EVTS	DOCUMENT ID		TECN	COMMENT

0.103 $\pm$ 0.036 $\pm$ 0.028	18	[25] ACTON	92N	OPAL	$e^+e^- \to Z$
• • • We do not use the following data for averages, fits, limits, etc. • • •					
0.13 $\pm$0.04 $\pm$0.04	27	[26] BUSKULIC	92E	ALEP	$e^+e^- \to Z$

[23] BUSKULIC 95O use $D_s\ell$ correlations. The measured product branching ratio is $B(\overline{b} \to B_s) \times B(B_s \to D_s^- \ell^+ \nu_\ell \text{anything}) = (0.82 \pm 0.09^{+0.13}_{-0.14})\%$ assuming $B(D_s \to \phi\pi) = (3.5 \pm 0.4) \times 10^{-2}$ and PDG 1994 values for the relative partial widths to the six other D_s channels used in this analysis. Combined with results from $\Upsilon(4S)$ experiments this can be used to extract $B(\overline{b} \to B_s) = (11.0 \pm 1.2^{+2.5}_{-2.6})\%$. We evaluate using our current values $B(\overline{b} \to B_s^0) = 0.107 \pm 0.014$ and $B(D_s \to \phi\pi) = 0.036 \pm 0.009$. Our first error is their experiment's and our second error is that due to $B(\overline{b} \to B_s^0)$ and $B(D_s \to \phi\pi)$.

[24] ABREU 92M measured muons only and obtained product branching ratio $B(Z \to b\text{or } \overline{b}) \times B(\overline{b} \to B_s) \times B(B_s \to D_s \mu^+ \nu_\mu \text{anything}) \times B(D_s \to \phi\pi) = (18 \pm 8) \times 10^{-5}$. We evaluate using our current values $B(\overline{b} \to B_s^0) = 0.107 \pm 0.014$ and $B(D_s \to \phi\pi) = 0.036 \pm 0.009$. Our first error is their experiment's and our second error is that due to $B(\overline{b} \to B_s^0)$ and $B(D_s \to \phi\pi)$. We use $B(Z \to b\text{or } \overline{b}) = 2B(Z \to b\overline{b}) = 2 \times (0.2212 \pm 0.0019)$.

[25] ACTON 92N is measured using $D_s \to \phi\pi^+$ and $K^*(892)^0 K^+$ events. The product branching fraction measured is measured to be $B(\overline{b} \to B_s^0) B(B_s^0 \to D_s^- \ell^+ \nu_\ell \text{anything}) \times B(D_s^- \to \phi\pi^-) = (3.9 \pm 1.1 \pm 0.8) \times 10^{-4}$. We evaluate using our current values $B(\overline{b} \to B_s^0) = 0.107 \pm 0.014$ and $B(D_s \to \phi\pi) = 0.036 \pm 0.009$. Our first error is their experiment's and our second error is that due to $B(\overline{b} \to B_s^0)$ and $B(D_s \to \phi\pi)$.

[26] BUSKULIC 92E is measured using $D_s \to \phi\pi^+$ and $K^*(892)^0 K^+$ events. They use $2.7 \pm 0.7\%$ for the $\phi\pi^+$ branching fraction. The average product branching fraction is measured to be $B(\overline{b} \to B_s^0) B(B_s^0 \to D_s^- \ell^+ \nu_\ell \text{anything}) = 0.020 \pm 0.0055^{+0.005}_{-0.006}$. We evaluate using our current values $B(\overline{b} \to B_s^0) = 0.107 \pm 0.014$ and $B(D_s \to \phi\pi) = 0.036 \pm 0.009$. Our first error is their experiment's and our second error is that due to $B(\overline{b} \to B_s^0)$ and $B(D_s \to \phi\pi)$. Superseded by BUSKULIC 95O.

$0.56\pm0.21^{+0.02}_{-0.04}$	19	ABE	95Z	CDF	$p\overline{p}$ at 1.8 TeV

[61] AFFOLDER 00N measurements are based on 40 B_s^0 candidates obtained from a data sample of 89 pb^{-1}. The P-wave fraction is found to be 0.23 ± 0.19 ± 0.04.

B_s^0-$\overline{B}_s^0$ MIXING

For a discussion of B_s^0-$\overline{B}_s^0$ mixing see the note on "B^0-$\overline{B}^0$ Mixing" in the B^0 Particle Listings above.

χ_s is a measure of the time-integrated B_s^0-$\overline{B}_s^0$ mixing probability that produced $B_s^0(\overline{B}_s^0)$ decays as a $\overline{B}_s^0(B_s^0)$. Mixing violates $\Delta B \neq 2$ rule.

$$\chi_s = \frac{x_s^2}{2(1+x_s^2)}$$

$$x_s = \frac{\Delta m_{B_s^0}}{\Gamma_{B_s^0}} = (m_{B_{sH}^0} - m_{B_{sL}^0})\,\tau_{B_s^0},$$

where H, L stand for heavy and light states of two B_s^0 CP eigenstates and $\tau_{B_s^0} = \frac{1}{0.5(\Gamma_{B_{sH}^0}+\Gamma_{B_{sL}^0})}$.

$\Delta m_{B_s^0} = m_{B_{sH}^0} - m_{B_{sL}^0}$

$\Delta m_{B_s^0}$ is a measure of 2π times the B_s^0-$\overline{B}_s^0$ oscillation frequency in time-dependent mixing experiments.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account corrections between the measurements.

> 1.8	95	[75] BUSKULIC	94B	ALEP	$e^+e^- \to Z$

[62] Events with a high transverse momentum lepton were removed and an inclusively reconstructed vertex was required.

[63] ABE 03 uses the novel "charge dipole" technique to reconstruct separate secondary and tertiary vertices originating from the $B \to D$ decay chain. The analysis excludes $\Delta m_s < 4.9\ ps^{-1}$ and $7.9 < \Delta m_s < 10.3\ ps^{-1}$.

[64] Three analyses based on complementary event selections: (1) fully-reconstructed hadronic decays; (2) semileptonic decays with D_s exclusively reconstructed; (3) inclusive semileptonic decays.

[65] ABE 02V uses exclusively reconstructed D_s^- mesons and excludes $\Delta m_s < 1.4\ ps^{-1}$ and $2.4 < \Delta m_s < 5.3\ ps^{-1}$ at 95%CL.

[66] Uses fully or partially reconstructed $D_s\ell$ vertices and a mixing tag as a flavor tagging.

[67] Uses $D_s^-\ell^+$, and $\phi\ell^+$ vertices, and a multi-variable discriminant as a flavor tagging.

[68] Uses inclusive D_s vertices and fully reconstructed B_s decays and a multi-variable discriminant as a flavor tagging.

[69] Uses ℓ-$Q_{\rm hem}$ and ℓ-ℓ.

[70] ABE 99J uses $\phi\ell$-ℓ correlation.

[71] ABE 99D assumes $\tau_{B_s^0} = 1.55 \pm 0.05$ ps and $\Delta\Gamma/\Delta m = (5.6 \pm 2.6) \times 10^{-3}$.

[72] BARATE 99J uses combination of an inclusive lepton and D_s^--based analyses.

[73] BARATE 98C combines results from $D_s h$-$\ell/Q_{\rm hem}$, $D_s h$-K in the same side, $D_s\ell$-$\ell/Q_{\rm hem}$ and $D_s\ell$-K in the same side.

[74] Uses ℓ-$Q_{\rm hem}$.

[75] Uses ℓ-ℓ.

[76] ADAM 97 combines results from $D_s\ell$-$Q_{\rm hem}$, ℓ-$Q_{\rm hem}$, and ℓ-ℓ.

[77] BUSKULIC 96M uses D_s lepton correlations and lepton, kaon, and jet charge tags.

[78] BUSKULIC 95J uses ℓ-$Q_{\rm hem}$. They find $\Delta m_s > 5.6$ [> 6.1] for f_s=10% [12%]. We interpolate to our central value f_s=10.5%.

$x_s = \Delta m_{B_s^0}/\Gamma_{B_s^0}$

This is derived by the Heavy Flavor Averaging Group (HFAG) from the results on $\Delta m_{B_s^0}$ and "OUR EVALUATION" of the B_s^0 mean lifetime.

$0.46^{+0.18}_{-0.16}$ ±0.03	[3] ABE	98M	CDF	$p\overline{p}$ 1.8 TeV

[3] The lifetime is measured from the $J/\psi(1S)\ell$ decay vertices.

B_c^+ DECAY MODES × B($\overline{b} \to B_c$)

B_c^- modes are charge conjugates of the modes below.

	Mode	Fraction (Γ_i/Γ)	Confidence level
	The following quantities are not pure branching ratios; rather the fraction $\Gamma_i/\Gamma \times$ B($\overline{b} \to B_c$).		
Γ_1	$J/\psi(1S)\ell^+\nu_\ell$ anything	$(5.2^{+2.4}_{-2.1}) \times 10^{-5}$	
Γ_2	$J/\psi(1S)\pi^+$	$< 8.2 \times 10^{-5}$	90%
Γ_3	$J/\psi(1S)\pi^+\pi^+\pi^-$	$< 5.7 \times 10^{-4}$	90%
Γ_4	$J/\psi(1S)a_1(1260)$	$< 1.2 \times 10^{-3}$	90%
Γ_5	$D^*(2010)^+\overline{D}^0$	$< 6.2 \times 10^{-3}$	90%

B_c^+ BRANCHING RATIOS

$\Gamma(J/\psi(1S)\ell^+\nu_\ell \text{ anything})/\Gamma_{\text{total}} \times$ B($\overline{b} \to B_c$) — $\Gamma_1/\Gamma \times$ B

VALUE	CL%	DOCUMENT ID		TECN	COMMENT
$(5.2^{+2.4}_{-2.1}) \times 10^{-5}$		[4] ABE	98M	CDF	$p\overline{p}$ 1.8 TeV
• • • We do not use the following data for averages, fits, limits, etc. • • •					
$< 1.6 \times 10^{-4}$	90	[5] ACKERSTAFF	98O	OPAL	$e^+e^- \to Z$
$< 1.9 \times 10^{-4}$	90	[6] ABREU	97E	DLPH	$e^+e^- \to Z$
$< 1.2 \times 10^{-4}$	90	[7] BARATE	97H	ALEP	$e^+e^- \to Z$

[4] ABE 98M result is derived from the measurement of $[\sigma(B_c)\times$B$(B_c \to J/\psi(1S)\ell\nu_\ell)]$ / $[\sigma(B^+)\times$B$(B^+ \to J/\psi(1S)K^+)] = 0.132^{+0.041}_{-0.037}(\text{stat}) \pm 0.031(\text{sys})^{+0.032}_{-0.020}(\text{lifetime})$ by using PDG 98 values of B$(b \to B^+)$ and B$(B^+ \to J/\psi(1S)K^+)$.

[5] ACKERSTAFF 98O reports B$(Z \to B_c X)$/B$(Z \to q\overline{q})\times$B$(B_c \to J/\psi(1S)\ell\nu_\ell) < 6.95 \times 10^{-5}$ at 90%CL. We rescale to our PDG 98 values of B$(Z \to b\overline{b})$.

[6] ABREU 97E value listed is for an assumed $\tau_{B_c} = 0.4$ ps and improves to 1.6×10^{-4} for $\tau_{B_c} = 1.4$ ps.

[7] BARATE 97H reports B$(Z \to B_c X)$/B$(Z \to q\overline{q})\cdot$B$(B_c \to J/\psi(1S)\ell\nu_\ell) < 5.2\times 10^{-5}$ at 90%CL. We rescale to our PDG 96 values of B$(Z \to b\overline{b})$. A $B_c^+ \to J/\psi(1S)\mu^+\nu_\mu$ candidate event is found, compared to all the known background sources 2×10^{-3}, which gives $m_{B_c} = 5.96^{+0.25}_{-0.19}$ GeV and $\tau_{B_c} = 1.77 \pm 0.17$ ps.

$\Gamma(J/\psi(1S)\pi^+)/\Gamma_{\text{total}} \times$ B($\overline{b} \to B_c$) — $\Gamma_2/\Gamma \times$ B

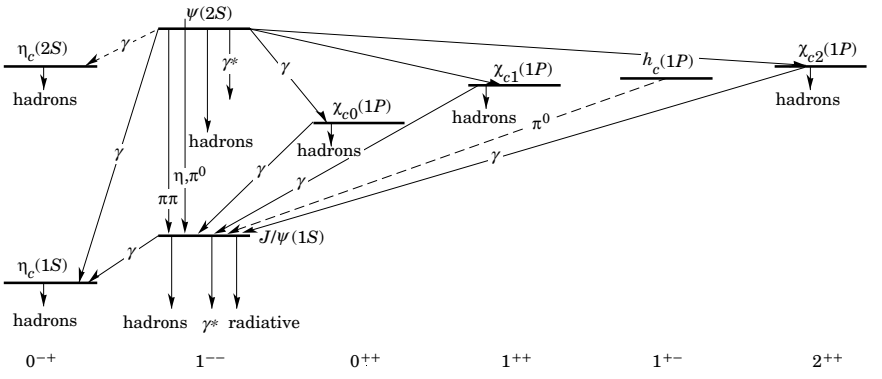
$c\overline{c}$ MESONS

THE CHARMONIUM SYSTEM



The current state of knowledge of the charmonium system and transitions, as interpreted by the charmonium model. Uncertain states and transitions are indicated by dashed lines. The notation γ^* refers to decay processes involving intermediate virtual photons, including decays to e^+e^- and $\mu^+\mu^-$.

$\eta_c(1S)$

$I^G(J^{PC}) = 0^+(0^{-+})$

$\mathbf{4.0^{+3.5}_{-3.2}}$	BAGLIN	89	SPEC	$\overline{p}p \to K^+K^-K^+K^-$

[25] The quoted branching ratios use $B(J/\psi(1S) \to \gamma\eta_c(1S)) = 0.0127 \pm 0.0036$. Where relevant, the error in this branching ratio is treated as a common systematic in computing averages.

[26] Using $B(B^+ \to \eta_c K^+) = (1.25 \pm 0.12^{+0.10}_{-0.12}) \times 10^{-3}$ from FANG 03 and $B(\eta_c \to K\overline{K}\pi) = (5.5 \pm 1.7) \times 10^{-2}$.

[27] We are assuming $B(a_0(980) \to \eta\pi) > 0.5$.

[28] Average from $K^+K^-\pi^0$ and $K^\pm K^0_S\pi^\mp$ decay channels.

[29] Estimated using $B(\psi(2S) \to \gamma\eta_c(1S)) = 0.0028 \pm 0.0006$.

[30] Normalized to the sum of $B(\eta_c \to K^\pm K^0_S\pi^\mp)$, $B(\eta_c \to \phi\phi)$, $B(\eta_c \to K^+K^-\pi^+\pi^-)$, and $B(\eta_c \to 2\pi^+2\pi^-)$.

BRANCHING RATIOS OF $\psi(2S)$ AND $\chi_{c0,1,2}$

Written March 2002 by J.J. Hernández-Rey (IFIC, Valencia), S. Navas (University of Granada), and C. Patrignani (INFN, Genova). Updated Nov 2003

Since 2002, the treatment of the branching ratios of the $\psi(2S)$ and $\chi_{c0,1,2}$ has undergone an important restructuring.

When measuring a branching ratio experimentally, it is not always possible to normalize the number of events observed in the corresponding decay mode to the total number of particles produced. Therefore, the experimenters sometimes report the number of observed decays with respect to another decay mode of the same or another particle in the relevant decay chain. This is actually equivalent to measuring combinations of branching fractions of several decay modes.

To extract the branching ratio of a given decay mode, the collaborations use some previously reported measurements of the required branching ratios. However, the values are frequently taken from the *Review of Particle Physics* (RPP), which in turn uses the branching ratio reported by the experiment in the following edition, giving rise either to correlations or to plain vicious circles.

One of these inconsistencies within the $\psi(2S)$ decays was reported in Ref. 10. To obtain the branching ratios of the decay modes $\psi(2S) \to J/\psi(1S)\,\pi^+\,\pi^-$, $\psi(2S) \to J/\psi(1S)\,\pi^0\,\pi^0$, and $\psi(2S) \to J/\psi(1S)\,\eta$, E760 Collaboration [2] used the value of $\mathrm{B}(\psi(2S) \to J/\psi(1S)\ anything)$ given in Ref. 6, obtained with a fit that included the above decays. The values obtained in this way in Ref. 2 were subsequently used in the 1998 edition of RPP [7] as new entries in the same fit.

A more subtle correlation, among others, was pointed out in Ref. 5. BES Collaboration [3] obtained the value of $B(\chi_{c0} \to p\,\overline{p})$ in e^+e^- collisions from the number of observed decays $\psi(2S) \to \gamma\,\chi_{c0} \to \gamma\,p\,\overline{p}$, and the total number of $\psi(2S)$ produced, which was estimated in turn from the observed number of decays of the type $\psi(2S) \to J/\psi(1S)\,\pi^+\,\pi^-$ [4]. To this end, they used the values of the branching ratios of $\psi(2S) \to J/\psi(1S)\,\pi^+\,\pi^-$ and $\psi(2S) \to \gamma\,\chi_{c0}$ given in the 1996 edition of RPP [6]. On the other hand, in $p\,\overline{p}$ collision experiments (*e.g.*, E835 Collaboration [1]), the value of $\mathrm{B}(\psi(2S) \to \gamma\,\chi_{c0})$ was entered inversely in the determination of $\mathrm{B}(\chi_{c0} \to p\,\overline{p})$ from a measurement of $\Gamma(\chi_{c0} \to p\,\overline{p}) \times \mathrm{B}(\chi_{c0} \to \gamma\,J/\psi(1S))$, since it was used to derive $\mathrm{B}(\chi_{c0} \to \gamma\,J/\psi(1S))$. Therefore, a hidden correlation was introduced in RPP when quoting the values of the corresponding unfolded magnitudes for both types of experiments.

The way to avoid these dependencies and correlations is to extract the branching ratios through a fit that uses the truly measured combinations of branching fractions and partial widths. This fit, in fact, should involve decays from the four concerned particles, $\psi(2S)$, χ_{c0}, χ_{c1}, and χ_{c2}, and occasionally some combinations of branching ratios of more than one of them. This is what is done since the 2002 edition [9].

The PDG policy is to quote the results of the collaborations in a manner as close as possible to what appears in their original publications. However, in order to avoid the problems mentioned above, we had in some cases to work out the values originally measured, using the number of events and detection efficiencies given by the collaborations, or rescaling back the published results. The information was sometimes spread over several articles, and some articles referred to papers still unpublished, which in turn contained the relevant numbers in footnotes.

Even though the experimental collaborations are entitled to extract whatever branching ratios they consider appropriate by using other published results, we would like to encourage them to also quote explicitly in their articles the actual quantities measured, so that they can be used directly in averages and fits of different experimental determinations.

To inform the reader how we computed some of the values used in this edition of RPP, we use footnotes to indicate the branching ratios actually given by the experiments and the quantities they use to derive them from the true combination of branching ratios actually measured.

None of the branching ratios of the $\chi_{c0,1,2}$ are measured independently of the $\psi(2S)$ radiative decays. We tried to identify those branching ratios which can be correlated in a non-trivial way, and although we cannot preclude the existence of other cases, we are confident that the most relevant correlations have already been removed. Nevertheless, correlations in the errors of different quantities measured by the same experiment have not been taken into account.

The relatively high χ^2 of the fit, 1.5 per d.o.f., can be traced back to a few specific discrepancies in the data. No rescaling of errors has been applied.

FIT INFORMATION

This is an overall fit to 4 total widths, 1 partial width, 6 combinations of partial widths, 6 branching ratios, and 28 combinations of branching ratios. Of the latter, 13 involve decays of more than one particle. The overall fit uses 88 measurements to determine 24 parameters. The overall fit has a χ^2 of 95.8 for 64 degrees of freedom.

[5] Rescaled by us using $B(\psi(2S) \to \gamma\chi_{c0}) = (8.6 \pm 0.7)\%$ and $B(\psi(2S) \to J/\psi(1S)\pi^+\pi^-) = 0.317 \pm 0.011$.

[6] Calculated using $B(\psi(2S) \to \gamma\chi_{c0}(1P)) = 0.094$; the errors do not contain the uncertainty in the $\psi(2S)$ decay.

[7] Calculated using $B(\psi(2S) \to \gamma\chi_{c0}(1P)) = 0.093 \pm 0.008$.

[8] We have multiplied $\pi^0\pi^0$ measurement by 3 to obtain $\pi\pi$.

[9] We have multiplied $B(p\overline{p})\cdot B(\pi^0\pi^0)$ measurement by 3 to obtain $B(p\overline{p})\cdot B(\pi\pi)$.

[1] Mass central value and systematic error recalculated by us according to Eq. (16) in ARMSTRONG 93B, using the value for the $\psi(2S)$ mass from AULCHENKO 03.
[2] Using mass of $\psi(2S) = 3686.0$ MeV.
[3] $J/\psi(1S)$ mass constrained to 3097 MeV.
[4] Assuming $\psi(2S)$ mass = 3686 MeV and $J/\psi(1S)$ mass = 3097 MeV.
[5] Mass value shifted by us by amount appropriate for $\psi(2S)$ mass = 3686 MeV and $J/\psi(1S)$ mass = 3097 MeV.
[6] From a simultaneous fit to radiative and hadronic decay channels.

VALUE (eV)	CL%	DOCUMENT ID	TECN	COMMENT
<43	90	BRANDELIK 79C	DASP	e^+e^-

[8] From a simultaneous fit to e^+e^-, $\mu^+\mu^-$, and hadronic channel, assuming $\Gamma_e = \Gamma_\mu = \Gamma_\tau/0.38847$.

$\psi(2S)$ Γ(i)$\Gamma(e^+e^-)/\Gamma$(total)

This combination of a partial width with the partial width into e^+e^- and with the total width is obtained from the integrated cross section into channel$_i$ in the e^+e^- annihilation. We list only data that have not been used to determine the partial width Γ(i) or the branching ratio Γ(i)/total.

[27] Angular distribution $(1+\cos^2\theta)$ assumed.
[28] Angular distribution $(1-0.189\cos^2\theta)$ assumed.
[29] Valid for isotropic distribution of the photon.
[30] Angular distribution $(1-0.052\cos^2\theta)$ assumed.
[31] Restated by us using $B(\psi(2S) \to \mu^+\mu^-) = 0.0077$.
[32] Restated by us using total decay width 228 keV.
[33] The value is normalized to the branching ratio for $\Gamma(J/\psi(1S)\eta)/\Gamma_{total}$.
[34] Normalized to $B(\psi(2S) \to J/\psi\pi^+\pi^-) = 0.305 \pm 0.016$.
[35] Combining the results from $\pi^+\pi^-$ and $\pi^0\pi^0$ decay modes.
[36] Includes unknown branching fractions to K^+K^- or $K^0_S K^0_S$. We have multiplied the K^+K^- result by a factor of 2 and the $K^0_S K^0_S$ result by a factor of 4 to obtain the $K\overline{K}$ result.
[37] Includes unknown branching fraction $\eta(1405) \to K\overline{K}\pi$.

$\psi(2S)$ CROSS-PARTICLE BRANCHING RATIOS

For measurements involving $B(\psi(2S) \to \gamma\chi_{cJ}(1P))\times B(\chi_{cJ}(1P) \to X)$ see the corresponding entries in the $\chi_{cJ}(1P)$ sections.

$\psi(3836)$

$I^G(J^{PC}) = 0^-(2^{--})$

OMITTED FROM SUMMARY TABLE

Quantum numbers are not established.

Seen in $\pi^\pm$Li interactions by ANTONIAZZI 94 as a peak in the invariant mass of the $J/\psi(1S)\pi^+\pi^-$ system. Possibly seen also in pLi interactions. Interpretation as a $^3D_2$ (2^{--}) charmonium state favored. Not seen by BAI 98E in e^+e^- interactions. Needs confirmation.

$X(3872)$

$I^G(J^P) = ?^?(?^?)$

OMITTED FROM SUMMARY TABLE

Seen by CHOI 03 in $B \to K\pi^+\pi^- J/\psi(1S)$ decays as a narrow peak in the invariant mass distribution of the $\pi^+\pi^- J/\psi(1S)$ final state, but not seen in the $\gamma\chi_{c1}$ final state of these decays. Possibly absent in the invariant mass spectrum of the final state $\pi^+\pi^- J/\psi(1S)$ in e^+e^- collisions. Interpretation as a 1^{--} charmonium state not favored.

Quantum numbers are not established.

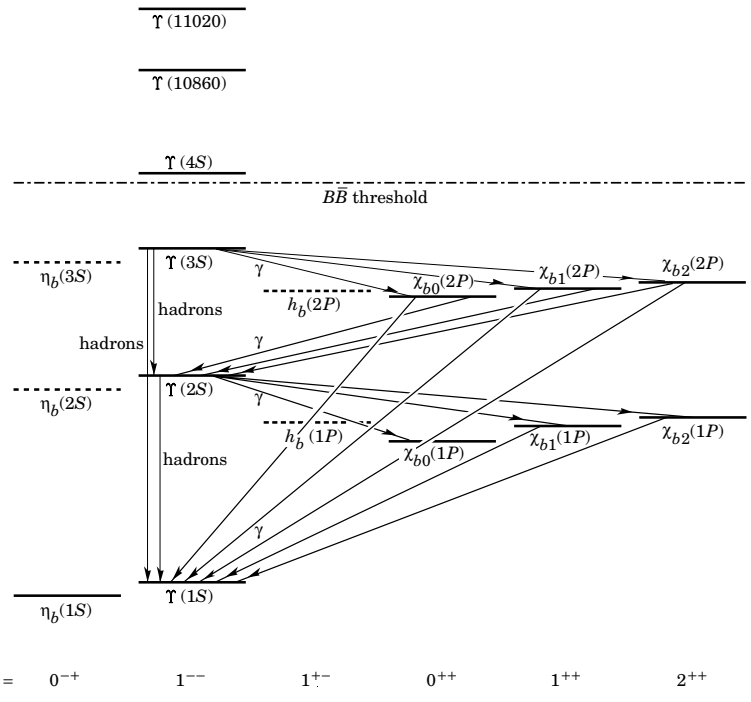
$b\bar{b}$ MESONS

THE BOTTOMONIUM SYSTEM



The level scheme of the $b\bar{b}$ states showing experimentally established states with solid lines. Singlet states are called η_b and h_b, triplet states Υ and χ_{bJ}. In parentheses it is sufficient to give the radial quantum number and the orbital angular momentum to specify the states with all their quantum numbers. *E.g.*, $h_b(2P)$ means 2^1P_1 with $n = 2$, $L = 1$, $S = 0$, $J = 1$, $PC = +-$. If found, D-wave states would be called $\eta_b(nD)$ and $\Upsilon_J(nD)$, with J = 1,2,3 and $n = 1, 2, 3, 4, \cdots$. For the χ_b states, the spins of only the $\chi_{b2}(1P)$ and $\chi_{b1}(1P)$ have been experimentally established. The spins of the other χ_b are given as the preferred values, based on the quarkonium models. The figure also shows the observed hadronic and radiative transitions.

WIDTH DETERMINATIONS OF THE Υ STATES

As is the case for the $J/\psi(1S)$ and $\psi(2S)$, the full widths of the $b\bar{b}$ states $\Upsilon(1S)$, $\Upsilon(2S)$, and $\Upsilon(3S)$ are not directly measurable, since they are much narrower than the energy resolution of the e^+e^- storage rings where these states are produced. The common indirect method to determine Γ starts from

$$\Gamma = \Gamma_{\ell\ell}/B_{\ell\ell} \ , \tag{1}$$

where $\Gamma_{\ell\ell}$ is one leptonic partial width and $B_{\ell\ell}$ is the corresponding branching fraction (ℓ = e, μ, or τ). One then assumes e-μ-τ universality and uses

$$\Gamma_{\ell\ell} = \Gamma_{ee}$$

$$B_{\ell\ell} = \text{average of } B_{ee},\ B_{\mu\mu},\ \text{and } B_{\tau\tau} \ . \tag{2}$$

The electronic partial width Γ_{ee} is also not directly measurable at e^+e^- storage rings, only in the combination $\Gamma_{ee}\Gamma_{\rm had}/\Gamma$, where $\Gamma_{\rm had}$ is the hadronic partial width and

$$\Gamma_{\rm had} + 3\Gamma_{ee} = \Gamma \ . \tag{3}$$

This combination is obtained experimentally from the energy-integrated hadronic cross section

$$\int_{\text{resonance}} \sigma(e^+e^- \to \Upsilon \to \text{hadrons})dE$$

$$= \frac{6\pi^2}{M^2}\frac{\Gamma_{ee}\Gamma_{\rm had}}{\Gamma}C_r = \frac{6\pi^2}{M^2}\frac{\Gamma_{ee}^{(0)}\Gamma_{\rm had}}{\Gamma}C_r^{(0)} \ , \tag{4}$$

where M is the Υ mass, and C_r and $C_r^{(0)}$ are radiative correction factors. C_r is used for obtaining Γ_{ee} as defined in Eq. (1), and contains corrections from all orders of QED for describing $(b\bar{b}) \to e^+e^-$. The lowest order QED value $\Gamma_{ee}^{(0)}$, relevant for comparison with potential-model calculations, is defined by the

lowest order QED graph (Born term) alone, and is about 7% lower than Γ_{ee}.

The Listings give experimental results on B_{ee}, $B_{\mu\mu}$, $B_{\tau\tau}$, and $\Gamma_{ee}\Gamma_{\rm had}/\Gamma$. The entries of the last quantity have been re-evaluated consistently using the correction procedure of KURAEV 85. The partial width Γ_{ee} is obtained from the average values for $\Gamma_{ee}\Gamma_{\rm had}/\Gamma$ and $B_{\ell\ell}$ using

$$\Gamma_{ee} = \frac{\Gamma_{ee}\Gamma_{\rm had}}{\Gamma(1-3B_{\ell\ell})} \ . \qquad (5)$$

The total width Γ is then obtained from Eq. (1). We do not list Γ_{ee} and Γ values of individual experiments. The Γ_{ee} values in the Meson Summary Table are also those defined in Eq. (1).

$\eta_b(1S)$

$I^G(J^{PC}) = 0^+(0^{-+})$

OMITTED FROM SUMMARY TABLE

Quantum numbers shown are quark-model predictions. One event is observed with the expected background of one. Needs confirmation.

$\chi_{b0}(1P)$

$I^G(J^{PC}) = 0^+(0^{++})$
J needs confirmation.

Observed in radiative decay of the $\Upsilon(2S)$, therefore $C = +$. Branching ratio requires E1 transition, M1 is strongly disfavored, therefore $P = +$.

$\chi_{b0}(2P)$

$I^G(J^{PC}) = 0^+(0^{++})$
J needs confirmation.

Observed in radiative decay of the $\Upsilon(3S)$, therefore $C = +$. Branching ratio requires E1 transition, M1 is strongly disfavored, therefore $P = +$.

$\chi_{b1}(2P)$

$I^G(J^{PC}) = 0^+(1^{++})$
J needs confirmation.

Observed in radiative decay of the $\Upsilon(3S)$, therefore $C = +$. Branching ratio requires E1 transition, M1 is strongly disfavored, therefore $P = +$.

NON-$q\overline{q}$ CANDIDATES

We include here mini-reviews and reference lists on gluonium and other non-$q\overline{q}$ candidates. See also the section on Further States for possible bound states.

NON-$q\overline{q}$ MESONS

Revised December 2003 by C. Amsler (University of Zürich).

The constituent quark model describes the observed meson spectrum as bound $q\overline{q}$ states grouped into SU(N) flavor multiplets (see our review on the quark model). However, the self-coupling of gluons in QCD suggests that additional mesons made of bound gluons (glueballs), or $q\overline{q}$-pairs with an excited gluon (hybrids), may exist. Multiquark color singlet states like $qq\overline{qq}$ or $qqq\overline{qqq}$ have also been predicted (JAFFE 77). Among the signatures naively expected for glueballs are (i) no place in $q\overline{q}$ nonets, (ii) enhanced production in gluon-rich channels such as central production and radiative $J/\psi(1S)$ decay, (iii) decay branching fractions incompatible with SU(N) predictions for $q\overline{q}$ states, and (iv) reduced $\gamma\gamma$ couplings. However, mixing effects with isoscalar $q\overline{q}$ mesons (AMSLER 96, ANISOVICH 97, WEINGARTEN 97, CLOSE 01B) and decay form factors (BARNES 97) may obscure these simple signatures.

Lattice calculations (BALI 93, SEXTON 95, MORNINGSTAR 99), QCD sum rules, flux tube, and constituent glue models agree that the lightest glueballs have quantum numbers $J^{PC} = 0^{++}$ and 2^{++}. On the lattice, the scale parameter (estimated from the string tension in heavy quark mesons) gives by extrapolation to zero lattice spacing a mass of 1611 $\pm$ 163 MeV for the ground state (0^{++}) glueball, while the first excited state (2^{++}) has a mass of 2232 $\pm$ 310 MeV (MICHAEL 97). Hence, the low-mass glueballs lie in the same mass region as ordinary isoscalar $q\overline{q}$ states, that is, in the mass range of the $1^3P_0(0^{++})$, 2^3P_2, 3^3P_2, and $1^3F_2(2^{++})$ $q\overline{q}$ states. The 0^{-+} state and exotic glueballs (with non-$q\overline{q}$ quantum numbers such as 0^{--}, 0^{+-}, 1^{-+}, 2^{+-}, *etc.*) are expected above 2 GeV (MORNINGSTAR 99).

The lattice calculations assume that the quark masses are infinite, and therefore neglect $q\overline{q}$ loops. However, one expects that glueballs will mix with nearby $q\overline{q}$ states of the same quantum numbers. The presence of a glueball mixed with $q\overline{q}$ would still lead to a supernumerary isoscalar in the SU(3) classification of $q\overline{q}$ mesons.

For earlier experimental searches, we refer to the Notes in the 1996 and 1998 issues of this *Review*. For a detailed recent review on exotic mesons, see AMSLER 04.

We first deal with non-$q\overline{q}$ candidates in the scalar sector. Five isoscalar resonances are well established: the very broad $f_0(600)$ (or σ), the $f_0(980)$, the broad $f_0(1370)$, and the comparatively narrow $f_0(1500)$ and $f_0(1710)$ (see the Note on "Scalar Mesons," and also AMSLER 98). The $f_0(1500)$ was observed in many experiments, *e.g.*, in π^-p reactions, in $\overline{p}p$ annihilations, in central collisions, in $J/\psi(1S)$ radiative decays, and in D_s decays (see the Meson Particle Listings). The $f_0(1710)$ decays mainly into $K\overline{K}$. This points to a mostly $s\overline{s}$ structure, although no signal was reported earlier in $K^-p \to K_SK_S\Lambda$ interactions (ASTON 88D). However, the assumption was that the spin would be 2. Also, the $f_0(1710)$ is not observed in $p\overline{p}$ annihilation (AMSLER 02), as expected from the OZI rule for an $s\overline{s}$ state.

In $\gamma\gamma$ collisions leading to K_SK_S (ACCIARRI 01H) and K^+K^- (ABE 04), a signal is observed at the $f_0(1710)$ mass. Spin 2 is preferred, but the isospin cannot be determined, hence, the signal is possibly coming from $a_2(1700)$. A spin 0 component from the $s\overline{s}$ $f_0(1710)$ is compatible with data.

On the other hand, $f_0(1500)$ is not observed in $\gamma\gamma \to K_SK_S$ nor $\pi^+\pi^-$ (BARATE 00E). The upper limit from $\pi^+\pi^-$ excludes a large $u\overline{u}+d\overline{d}$ content, and points to a mainly $s\overline{s}$ meson (AMSLER 02B). This is, however, in contradiction with the small $K\overline{K}$ decay branching ratio of $f_0(1500)$ (ABELE 96B,98, BARBERIS 99D). Hence, this state is hard to accommodate as a $q\overline{q}$ meson.

Since $f_0(1370)$ does not couple strongly to $s\overline{s}$ either (BARBERIS 99D), $f_0(1370)$ or $f_0(1500)$ appear to be supernumerary. Note that $f_0(1370)$ and $f_0(1500)$ have rather different 4π decay patterns. The former decays dominantly into two S-wave dipions, and the latter mostly into $\pi(1300)\pi$ (ABELE 01,01B). The narrow width of $f_0(1500)$, and its enhanced production at low transverse momentum transfer in central collisions (CLOSE 97,98B, KIRK 00) also favor $f_0(1500)$ to be non-$q\overline{q}$. In AMSLER 96, the ground state scalar nonet is made of $a_0(1450)$, $f_0(1370)$, $K_0^*(1430)$, and $f_0(1710)$. The isoscalars $f_0(1370)$ and $f_0(1710)$ contain a small fraction of glue, while $f_0(1500)$ is mostly gluonic. The light scalars $f_0(600)$, $f_0(980)$, $a_0(980)$, and $\kappa(800)$ are four-quark states or two-meson resonances (see AMSLER 04 for a review). In the mixing scheme of CLOSE 01B, which uses all recent data in central production and $p\overline{p}$ annihilation, glue is shared between $f_0(1370)$ and $f_0(1500)$, while $f_0(1710)$ remains mainly $s\overline{s}$.

Alternative mixing schemes have been proposed (see for example TORNQVIST 96, ANISOVICH 97, BOGLIONE 97, WEINGARTEN 97, MINKOWSKI 99).

As mentioned above, $a_0(980)$ and $f_0(980)$ could be four-quark states (JAFFE 77, ALFORD 00) or $K\overline{K}$ molecular states (WEINSTEIN 90, LOCHER 98) due to their strong affinity for $K\overline{K}$, in spite of their masses being very close to threshold. For $q\overline{q}$ states, the expected $\gamma\gamma$ widths (OLLER 97B, DELBOURGO 99) are not significantly larger than for molecular states (BARNES 85). A better filter is radiative $\phi(1020)$ decay to $a_0(980)$ and $f_0(980)$. Recent data (ALOISIO 02C, 02D) favor these mesons to be four-quark states (ACHASOV 00F). The $f_0(980)$ is strongly produced in D_s^+ decay (FRABETTI 97, AITALA 01A). Assuming a dominant Cabibbo favored $c \to s$ decay suggests a large $s\overline{s}$ component. However, the mainly $u\overline{u}+d\overline{d}$ $f_0(1370)$ is also strongly produced in D_s^+ decay, indicating that other graphs must contribute (CHENG 03B).

Two very narrow states, $D_{sJ}(2317)^{*\pm}$ and $D_{sJ}(2460)^{*\pm}$, were observed recently at the B-factories (AUBERT 03G, BESSON 03), the former with preferred spin 0^+, the latter with 1^+. They lie far below the predicted masses for the two expected

broad P-wave $c\overline{s}$ mesons. These states have hence been interpreted as four-quark states (CHENG 03C, TERASAKI 03) or DK (DK^*) molecules (BARNES 03). However, strong cusp effects due to the nearby closed DK, respectively DK^* thresholds, could shift their masses downwards and quench the observed widths, an effect similar to that occuring for the $a_0(980)$ and $f_0(980)$ mesons, which lie just below the $K\overline{K}$ threshold.

We now turn to the 2^{++} sector. The isoscalar $1^3P_2(2^{++})$ $q\overline{q}$ mesons, $f_2(1270)$, and $f_2'(1525)$, are well known. Above the $f_2'(1525)$, none of the reported isoscalars can be definitely assigned to the 2^3P_2, 3^3P_2, or 1^3F_2 nonets, and therefore, the identification of the 2^{++} glueball is premature. Three states appear to be solid. The $f_2(1565)$ observed in $\overline{p}p$ annihilation at rest (MAY 90, BERTIN 98) is perhaps the same state as $f_2(1640)$, reported to decay into $\omega\omega$ (ALDE 90, BAKER 99) and 4π (ADAMO 92). This could be one of the 2^3P_2 isoscalars or a nucleon-antinucleon resonance. The broad $f_2(1950)$ is observed by several experiments, *e.g.*, in central production (BARBERIS 00C) and in $\overline{p}p$ annihilation in flight (AMSLER 02). The large $\phi\phi$ cross section in $\overline{p}p$ just above threshold (EVANGELISTA 98) could be due to the production of the 2^{++} glueball, in accord with earlier observations in π^-N reactions (BOOTH 86, ETKIN 88) and in central collisions (BARBERIS 98).

There is no evidence for a narrow meson, $f_J(2220)$ (possibly a tensor) in $\overline{p}p$ annihilation (see the Note under the $f_J(2220)$ section). The measured partial width to $\overline{p}p$ in radiative $J/\psi(1S)$ decay (BAI 96B) is too large and inconsistent with the upper limit from $\overline{p}p$ annihilation into $\pi\pi$ (AMSLER 01).

Let us now deal with hybrid states. Hybrids may be viewed as $q\overline{q}$ mesons with a vibrating gluon flux tube. In contrast to glueballs, they can have isospin 0 and 1. The mass spectrum of hybrids with exotic (non-$q\overline{q}$) quantum numbers was predicted by ISGUR 85, while CLOSE 95 also deals with non-exotic quantum numbers. The ground state hybrids with quantum numbers (0^{-+}, 1^{-+}, 1^{--}, and 2^{-+}) are expected around 1.7 to 1.9 GeV. Lattice calculations predict that the hybrid with exotic quantum numbers 1^{-+} lies at a mass of 1.9 ± 0.2 GeV (LACOCK 97, BERNARD 97). Most hybrids are rather broad, but some can be as narrow as 100 MeV (PAGE 99). They prefer to decay into a pair of S- and P-wave mesons.

A $J^{PC} = 1^{-+}$ exotic meson, $\pi_1(1400)$, was reported in $\pi^-p \to \eta\pi^-p$ (THOMPSON 97, CHUNG 99). It was observed as an interference between the angular momentum $L = 1$ and $L = 2$ $\eta\pi$ amplitudes, leading to a forward/backward asymmetry in the $\eta\pi$ angular distribution. This state was reported earlier in π^-p reactions (ALDE 88B), but ambiguous solutions in the partial-wave analysis were pointed out by PROKOSHKIN 95B,95C. A resonating 1^{-+} contribution to the $\eta\pi$ P wave is also required in the Dalitz plot analysis of $\overline{p}n$ annihilation into $\pi^-\pi^0\eta$ (ABELE 98B), and in $\overline{p}p$ annihilation into $\pi^0\pi^0\eta$ (ABELE 99). Mass and width are consistent with THOMPSON 97.

Another 1^{-+} state, $\pi_1(1600)$, decaying into $\rho\pi$ (ADAMS 98B) and $\eta'\pi$ (IVANOV 01), was reported in the reaction $\pi^-p \to \pi^-\rho^0(\pi^-\eta')n$. It was already observed earlier in the decay modes $\rho\pi$, $\eta'\pi$, and $b_1(1235)\pi$, but not $\eta\pi$ (GOUZ 92). A strong enhancement in the 1^{-+} $\eta'\pi$ wave, compared to $\eta\pi$, was reported at this mass by BELADIDZE 93. DONNACHIE 98 suggests that a Deck-generated $\eta\pi$ background from final state rescattering in $\pi_1(1600)$ decay could mimic $\pi_1(1400)$. However, this mechanism is absent in $\overline{p}p$ annihilation. The $\eta\pi\pi$ data require $\pi_1(1400)$ and cannot accommodate a state at 1600 MeV (DUENNWEBER 99).

Thus, we now have evidence for two 1^{-+} exotics, $\pi_1(1400)$ and $\pi_1(1600)$, while the flux tube model and the lattice concur to predict a mass of about 1.9 GeV, where a signal had been reported earlier (LEE 94). As isovectors, $\pi_1(1400)$ and $\pi_1(1600)$ cannot be glueballs. The coupling to $\eta\pi$ of the former points to a four-quark state (see also CHUNG 02C), while the strong $\eta'\pi$ coupling of the latter is favored for hybrid states (CLOSE 87B, IDDIR 01). Its mass is not far below the lattice prediction.

Finally, 0^{-+}, 1^{--}, and 2^{-+} hybrids were also reported. The $\pi(1800)$ decays mostly to a pair of S- and P-wave mesons (AMELIN 95B), in line with expectations for a 0^{-+} hybrid meson. This meson is also rather narrow if interpreted as the second radial excitation of the pion. The evidence for 1^{--} hybrids required in e^+e^- annihilation and in τ decays has been discussed by DONNACHIE 99. The $\rho(1900)$ seems too narrow for a $q\overline{q}$ radial excitation. A candidate for the 2^{-+} hybrid, the $\eta_2(1870)$, was reported in $\gamma\gamma$ interactions (KARCH 92), in $\overline{p}p$ annihilation (ADOMEIT 96), and in central production (BARBERIS 97B). The near degeneracy of $\eta_2(1645)$ and $\pi_2(1670)$ suggests ideal mixing in the 2^{-+} $q\overline{q}$ nonet, and hence, the second isoscalar should be mainly $s\overline{s}$. However, $\eta_2(1870)$ decays mainly to $a_2(1320)\pi$ and $f_2(1270)\pi$ (ADOMEIT 96), with a relative rate compatible with a hybrid state (CLOSE 95).

$|m_p - m_{\overline{p}}|/m_p$

A test of *CPT* invariance. Note that the comparison of the $\overline{p}$ and p charge-to-mass ratio, given in the next data block, is much better determined.

VALUE	CL%	DOCUMENT ID		TECN	COMMENT
< 1.0 × 10^{-8}	90	[1] HORI	03	SPEC	$\overline{p}e^-$ ^{4}He and $\overline{p}e^-$ ^{3}He
• • • We do not use the following data for averages, fits, limits, etc. • • •					
< 6 × 10^{-8}	90	[1] HORI	01	SPEC	$\overline{p}e^-$ He atom
< 5 × 10^{-7}		[2] TORII	99	SPEC	$\overline{p}e^-$ He atom

[1] HORI 01 and HORI 03 use the more-precisely-known constraint on the $\overline{p}$ charge-to-mass ratio of GABRIELSE 99 (see below) to get their results. Their results are not independent of the HORI 01 and HORI 03 values for $|q_p + q_{\overline{p}}|/e$, below.

[2] TORII 99 uses the more-precisely-known constraint on the $\overline{p}$ charge-to-mass ratio of GABRIELSE 95 (see below) to get this result. This is not independent of the TORII 99 value for $|q_p + q_{\overline{p}}|/e$, below.

$\overline{p}/p$ CHARGE-TO-MASS RATIO, $\left|\frac{q_{\overline{p}}}{m_{\overline{p}}}\right|/\left(\frac{q_p}{m_p}\right)$

A test of *CPT* invariance. Listed here are measurements involving the *inertial* masses. For a discussion of what may be inferred about the ratio of $\overline{p}$ and p *gravitational* masses, see ERICSON 90; they obtain an upper bound of 10^{-6}–10^{-7} for violation of the equivalence principle for $\overline{p}$s.

VALUE	DOCUMENT ID		TECN	COMMENT
0.99999999991 ± 0.00000000009	GABRIELSE	99	TRAP	Penning trap
• • • We do not use the following data for averages, fits, limits, etc. • • •				
1.0000000015 ± 0.0000000011	[3] GABRIELSE	95	TRAP	Penning trap
1.000000023 ± 0.000000042	[4] GABRIELSE	90	TRAP	Penning trap

[3] Equation (2) of GABRIELSE 95 should read $M(\overline{p})/M(p) = 0.999\,999\,9985\,(11)$ (G. Gabrielse, private communication).

[4] GABRIELSE 90 also measures $m_{\overline{p}}/m_{e^-} = 1836.152660 \pm 0.000083$ and $m_p/m_{e^-} = 1836.152680 \pm 0.000088$. Both are completely consistent with the 1986 CODATA (COHEN 87) value for m_p/m_{e^-} of 1836.152701 ± 0.000037.

$\left(\left|\frac{q_{\overline{p}}}{m_{\overline{p}}}\right| - \frac{q_p}{m_p}\right)/\frac{q_p}{m_p}$

A test of *CPT* invariance. Taken from the $\overline{p}/p$ charge-to-mass ratio, above.

VALUE	DOCUMENT ID
(−9 ± 9) × 10^{-11} OUR EVALUATION	

$|q_p + q_{\overline{p}}|/e$

A test of *CPT* invariance. Note that the comparison of the $\overline{p}$ and p charge-to-mass ratios given above is much better determined. See also a similar test involving the electron.

VALUE	CL%	DOCUMENT ID		TECN	COMMENT
< 1.0 × 10^{-8}	90	[5] HORI	03	SPEC	$\overline{p}e^-$ ^{4}He and $\overline{p}e^-$ ^{3}He
• • • We do not use the following data for averages, fits, limits, etc. • • •					
< 6 × 10^{-8}	90	[5] HORI	01	SPEC	$\overline{p}e^-$ He atom
< 5 × 10^{-7}		[6] TORII	99	SPEC	$\overline{p}e^-$ He atom
< 2 × 10^{-5}		[7] HUGHES	92	RVUE	

[5] HORI 01 and HORI 03 use the more-precisely-known constraint on the $\overline{p}$ charge-to-mass ratio of GABRIELSE 99 (see above) to get their results. Their results are not independent of the HORI 01 and HORI 03 values for $|m_p - m_{\overline{p}}|/m_p$, above.

[6] TORII 99 uses the more-precisely-known constraint on the $\overline{p}$ charge-to-mass ratio of GABRIELSE 95 (see above) to get this result. This is not independent of the TORII 99 value for $|m_p - m_{\overline{p}}|/m_p$, above.

[7] HUGHES 92 uses recent measurements of Rydberg-energy and cyclotron-frequency ratios.

$|q_p + q_e|/e$

See DYLLA 73 for a summary of experiments on the neutrality of matter. See also "*n* CHARGE" in the neutron Listings.

VALUE	DOCUMENT ID		COMMENT

12.1 ±1.1 ±0.5	[13] BEANE	03		EFT + γp
$11.82 \pm 0.98^{+0.52}_{-0.98}$	[14] BLANPIED	01	LEGS	$p(\vec{\gamma},\gamma)$, $p(\vec{\gamma},\pi^0)$, $p(\vec{\gamma},\pi^+)$
11.9 ±0.5 ±1.3	[15] OLMOSDEL...	01	CNTR	γp Compton scattering
12.1 ±0.8 ±0.5	[16] MACGIBBON	95	RVUE	global average
• • • We do not use the following data for averages, fits, limits, etc. • • •				
11.7 ±0.8 ±0.7	[17] BARANOV	01	RVUE	Global average
12.5 ±0.6 ±0.9	MACGIBBON	95	CNTR	γp Compton scattering
9.8 ±0.4 ±1.1	HALLIN	93	CNTR	γp Compton scattering
$10.62^{+1.25+1.07}_{-1.19-1.03}$	ZIEGER	92	CNTR	γp Compton scattering
10.9 ±2.2 ±1.3	[18] FEDERSPIEL	91	CNTR	γp Compton scattering

[13] BEANE 03 uses effective field theory and low-energy γp and γd Compton-scattering data. It also gets for the isoscalar polarizabilities $\alpha_N = (9.0 \pm 1.5^{+3.6}_{-0.8}) \times 10^{-4}$ fm^3 and $\beta_N = (1.7 \pm 1.5^{+1.4}_{-0.6}) \times 10^{-4}$ fm^3.

[14] BLANPIED 01 gives $\alpha_p + \beta_p$ and $\alpha_p - \beta_p$. The separate α_p and β_p are provided to us by A. Sandorfi. The first error above is statistics plus systematics; the second is from the model.

[15] This OLMOSDELEON 01 result uses the TAPS data alone, and does not use the (re-evaluated) sum-rule constraint that $\alpha + \beta = (13.8 \pm 0.4) \times 10^{-4}$ fm^3. See the paper for a discussion.

[16] MACGIBBON 95 combine the results of ZIEGER 92, FEDERSPIEL 91, and their own experiment to get a "global average" in which model errors and systematic errors are treated in a consistent way. See MACGIBBON 95 for a discussion.

[17] BARANOV 01 combines the results of 10 experiments from 1958 through 1995 to get a global average that takes into account both systematic and model errors and does not use the theoretical constraint on the sum $\alpha_p + \beta_p$.

[18] FEDERSPIEL 91 obtains for the (static) electric polarizability α_p, defined in terms of the induced electric dipole moment by $\mathbf{D} = 4\pi\epsilon_0\alpha_p\mathbf{E}$, the value $(7.0 \pm 2.2 \pm 1.3) \times 10^{-4}$ fm^3.

p MAGNETIC POLARIZABILITY β_p

The electric and magnetic polarizabilities are subject to a dispersion sum-rule constraint $\overline{\alpha} + \overline{\beta} = (14.2 \pm 0.5) \times 10^{-4}$ fm^3. Errors here are anticorrelated with those on $\overline{\alpha}_p$ due to this constraint.

[25] AHMED 04 looks for γ rays from the de-excitation of a residual ^{15}O* or ^{15}N* following the disappearance of a neutron or proton in ^{16}O.

[26] BACK 03 looks for decays of unstable nuclides left after N decays of parent ^{12}C, ^{13}C, ^{16}O nuclei. These are "invisible channel" limits.

[27] ZDESENKO 03 gets this limit on proton disappearance in deuterium by analyzing SNO data in AHMAD 02.

[28] AHMAD 02 (see its footnote 7) looks for neutrons left behind after the disappearance of the proton in deuterons.

[29] BERNABEI 00B looks for the decay of a $^{128}_{53}$I nucleus following the disappearance of a proton in the otherwise-stable $^{129}_{54}$Xe nucleus.

[30] EVANS 77 looks for the daughter nuclide ^{129}Xe from possible ^{130}Te decays in ancient Te ore samples.

[31] This mean-life limit has been obtained from a half-life limit by dividing the latter by ln(2) = 0.693.

[32] FLEROV 58 looks for the spontaneous fission of a ^{232}Th nucleus after the disappearance of one of its nucleons.

$\overline{p}$ MEAN LIFE

Of the two astrophysical limits here, that of GEER 00D involves considerably more refinements in its modeling. The other limits come from direct observations of stored antiprotons. See also "$\overline{p}$ Partial Mean Lives" after "p Partial Mean Lives," below, for exclusive-mode limits. The best (lifetime/branching fraction) limit there is 7×10^5 years, for $\overline{p} \to e^-\gamma$. We advance only the exclusive-mode limits to our Summary Tables.

LIMIT (years)	CL%	EVTS	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •						
$>8 \times 10^5$	90		[33] GEER	00D		$\overline{p}/p$ ratio, cosmic rays
>0.28			GABRIELSE	90	TRAP	Penning trap
>0.08	90	1	BELL	79	CNTR	Storage ring
$>1 \times 10^7$			GOLDEN	79	SPEC	$\overline{p}/p$ ratio, cosmic rays
$>3.7 \times 10^{-3}$			BREGMAN	78	CNTR	Storage ring

[33] GEER 00D uses agreement between a model of galactic $\overline{p}$ production and propagation and the observed $\overline{p}/p$ cosmic-ray spectrum to set this limit.

p DECAY MODES

See the "Note on Nucleon Decay" in our 1994 edition (Phys. Rev. **D50**, 1673) for a short review.

The "partial mean life" limits tabulated here are the limits on τ/B_i, where τ is the total mean life and B_i is the branching fraction for the mode in question. For N decays, p and n indicate proton and neutron partial lifetimes.

	Mode	Partial mean life (10^{30} years)	Confidence level
	Antilepton + meson

p PARTIAL MEAN LIVES

The "partial mean life" limits tabulated here are the limits on τ / B_i, where τ is the total mean life for the proton and B_i is the branching fraction for the mode in question.

Decaying particle: p = proton, n = bound neutron. The same event may appear under more than one partial decay mode. Background estimates may be accurate to a factor of two.

n

$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$ Status: ****

We have omitted some results that have been superseded by later experiments. See our earlier editions.

n MASS (atomic mass units u)

The mass is known much more precisely in u (atomic mass units) than in MeV. See the next data block.

VALUE (u)	DOCUMENT ID		TECN	COMMENT
1.00866491560 ± 0.00000000055	MOHR	04	RVUE	2002 CODATA value
• • • We do not use the following data for averages, fits, limits, etc. • • •				
1.008664915 78 ± 0.000000000055	MOHR	99	RVUE	1998 CODATA value
1.008665904 ± 0.000000014	COHEN	87	RVUE	1986 CODATA value

n MASS (MeV)

The mass is known much more precisely in u (atomic mass units) than in MeV. The conversion from u to MeV, 1 u = 931.494043±0.000080 MeV/c^2 (MOHR 04, the 2002 CODATA value), involves the relatively poorly known electronic charge.

VALUE (MeV)	DOCUMENT ID		TECN	COMMENT
939.565360 ± 0.000081	MOHR	04	RVUE	2002 CODATA value
• • • We do not use the following data for averages, fits, limits, etc. • • •				
939.565331 ± 0.000037	[1] KESSLER	99	SPEC	$np \to d\gamma$
939.565330 ± 0.000038	MOHR	99	RVUE	1998 CODATA value
939.56565 ± 0.00028	[2,3] DIFILIPPO	94	TRAP	Penning trap
939.56563 ± 0.00028	COHEN	87	RVUE	1986 CODATA value
939.56564 ± 0.00028	[3,4] GREENE	86	SPEC	$np \to d\gamma$
939.5731 ± 0.0027	[3] COHEN	73	RVUE	1973 CODATA value

[1] We use the 1998 CODATA u-to-MeV conversion factor (see the heading above) to get this mass in MeV from the much more precisely measured KESSLER 99 value of 1.00866491637 ± 0.00000000082 u.

[2] The mass is known much more precisely in u: m = 1.0086649235 ± 0.0000000023 u. We use the 1986 CODATA conversion factor to get the mass in MeV.

[3] These determinations are not independent of the $m_n - m_p$ measurements below.

[4] The mass is known much more precisely in u: m = 1.008664919 ± 0.000000014 u.

$\overline{n}$ MASS

VALUE (MeV)	EVTS	DOCUMENT ID		TECN	COMMENT
939.485 ± 0.051	59	[5] CRESTI	86	HBC	$\overline{p}p \to \overline{n}n$

[5] This is a corrected result (see the erratum). The error is statistical. The maximum systematic error is 0.029 MeV.

$(m_n - m_{\overline{n}})/m_n$

A test of CPT invariance. Calculated from the n and $\overline{n}$ masses, above.

VALUE	DOCUMENT ID

1.293429 ± 0.000036	COHEN	73	RVUE	1973 CODATA value

[6] Calculated by us from the MOHR 04 ratio m_n/m_p = 1.00137841870 ± 0.0000000058. In u, $m_n - m_p$ = (1.3884487 ± 0.0000006) × 10^{-3} u.

[7] Calculated by us from the MOHR 99 ratio m_n/m_p = 1.00137841887 ± 0.0000000058. In u, $m_n - m_p$ = (1.3884489 ± 0.0000006) × 10^{-3} u.

[8] Calculated by us from the COHEN 87 ratio m_n/m_p = 1.001378404 ± 0.000000009. In u, $m_n - m_p$ = 0.001388434 ± 0.000000009 u.

n MEAN LIFE

We now compile only direct measurements of the lifetime, not those inferred from decay correlation measurements. For the average, we only use measurements with an error less than 10 s.

Limits on lifetimes for *bound* neutrons are given in the section "*p* PARTIAL MEAN LIVES."

For an early review, see EROZOLIMSKII 89 and papers that follow it in an issue of NIM devoted to the "Proceedings of the International Workshop on Fundamental Physics with Slow Neutrons" (Grenoble 1989). For later reviews and/or commentary, see FREEDMAN 90, SCHRECKENBACH 92, and PENDLEBURY 93.

<16	90	ALTAREV	79	MRS	$d = (4.0 \pm 7.5) \times 10^{-25}$

[12] This HARRIS 99 result includes the result of SMITH 90. However, the averaging of the results of these two experiments has been criticized by LAMOREAUX 00.

n MEAN-SQUARE CHARGE RADIUS

The mean-square charge radius of the neutron, $\langle r_n^2 \rangle$, is related to the neutron-electron scattering length b_{ne} by $\langle r_n^2 \rangle = 3(m_e a_0/m_n) b_{ne}$, where m_e and m_n are the masses of the electron and neutron, and a_0 is the Bohr radius. Numerically, $\langle r_n^2 \rangle = 86.34\, b_{ne}$, if we use a_0 for a nucleus with infinite mass.

[14] KOSSERT 03 gets $\alpha_n - \beta_n = (9.8 \pm 3.6^{+2.1}_{-1.1} \pm 2.2) \times 10^{-4}$ fm^3, and uses $\alpha_n + \beta_n = (15.2 \pm 0.5) \times 10^{-4}$ fm^3 from OLMOSDELEON 01. Thus the errors on α_n and β_n are anti-correlated.

[15] LUNDIN 03 measures $\alpha_N - \beta_N = (6.4 \pm 2.4) \times 10^{-4}$ fm^3 and uses accurate values for α_p and α_p and a precise sum-rule result for $\alpha_n + \beta_n$. The second error is a model uncertainty, and errors on α_n and β_n are anticorrelated.

[16] KOLB 00 obtains this value with a lower limit of 7.6×10^{-4} fm^3 but no upper limit from this experiment alone. Combined with results of ROSE 90, the 1-σ range is $(7.6–14.0) \times 10^{-4}$ fm^3.

[17] KOESTER 95 uses natural Pb and the isotopes 208, 207, and 206. See this paper for a discussion of methods used by various groups to extract α_n from data.

LIMIT ON $n\overline{n}$ OSCILLATIONS

Mean Time for $n\overline{n}$ Transition in Vacuum

A test of ΔB=2 baryon number nonconservation. MOHAPATRA 80 and MOHAPATRA 89 discuss the theoretical motivations for looking for $n\overline{n}$ oscillations. DOVER 83 and DOVER 85 give phenomenological analyses. The best limits come from looking for the decay of neutrons bound in nuclei. However, these analyses require model-dependent corrections for nuclear effects. See KABIR 83, DOVER 89, ALBERICO 91, and GAL 00 for discussions. Direct searches for $n \to \overline{n}$ transitions using reactor neutrons are cleaner but give somewhat poorer limits. We include limits for both free and bound neutrons in the Summary Table.

$<8\times10^{-27}$	68	[25] NORMAN	96	RVUE	^{71}Ga → ^{71}Ge neutrals
• • • We do not use the following data for averages, fits, limits, etc. • • •					
$<9.7\times10^{-18}$	90	ROY	83	CNTR	^{113}Cd → ^{113m}Inneut.
$<7.9\times10^{-21}$		VAIDYA	83	CNTR	^{87}Rb → ^{87m}Srneut.
$<9\times10^{-24}$	90	BARABANOV	80	CNTR	^{71}Ga → ^{71}GeX
$<3\times10^{-19}$		NORMAN	79	CNTR	^{87}Rb → ^{87m}Srneut.

[25] NORMAN 96 gets this limit by attributing SAGE and GALLEX counting rates to the charge-nonconserving transition ^{71}Ga → ^{71}Ge+neutrals rather than to solar-neutrino reactions.

BARYON DECAY PARAMETERS

Written 1996 by E.D. Commins (University of California, Berkeley).

Baryon semileptonic decays

The typical spin-1/2 baryon semileptonic decay is described by a matrix element, the hadronic part of which may be written as:

$$\overline{B}_f \left[f_1(q^2)\gamma_\lambda + i\, f_2(q^2)\sigma_{\lambda\mu}q^\mu + g_1(q^2)\gamma_\lambda\gamma_5 + g_3(q^2)\gamma_5 q_\lambda \right] B_i \ . \quad (1)$$

Here B_i and $\overline{B}_f$ are spinors describing the initial and final baryons, and $q = p_i - p_f$, while the terms in f_1, f_2, g_1, and g_3 account for vector, induced tensor ("weak magnetism"), axial vector, and induced pseudoscalar contributions [1]. Second-class current contributions are ignored here. In the limit of zero momentum transfer, f_1 reduces to the vector coupling constant g_V, and g_1 reduces to the axial-vector coupling constant g_A. The latter coefficients are related by Cabibbo's theory [2], generalized to six quarks (and three mixing angles) by Kobayashi and Maskawa [3]. The g_3 term is negligible for transitions in which an $e^\pm$ is emitted, and gives a very small correction, which can be estimated by PCAC [4], for $\mu^\pm$ modes. Recoil effects include weak magnetism, and are taken into account adequately by considering terms of first order in

$$\delta = \frac{m_i - m_f}{m_i + m_f} \ , \quad (2)$$

where m_i and m_f are the masses of the initial and final baryons.

The experimental quantities of interest are the total decay rate, the lepton-neutrino angular correlation, the asymmetry coefficients in the decay of a polarized initial baryon, and the polarization of the decay baryon in its own rest frame for an unpolarized initial baryon. Formulae for these quantities are derived by standard means [5] and are analogous to formulae for nuclear beta decay [6]. We use the notation of Ref. 6 in the Listings for neutron beta decay. For comparison with experiments at higher q^2, it is necessary to modify the form factors at $q^2 = 0$ by a "dipole" q^2 dependence, and for high-precision comparisons to apply appropriate radiative corrections [7].

The ratio g_A/g_V may be written as

$$g_A/g_V = |g_A/g_V|\, e^{i\phi_{AV}} \ . \quad (3)$$

The presence of a "triple correlation" term in the transition probability, proportional to $\mathrm{Im}(g_A/g_V)$ and of the form

$$\boldsymbol{\sigma}_i \cdot (\mathbf{p}_\ell \times \mathbf{p}_\nu) \quad (4)$$

for initial baryon polarization or

$$\boldsymbol{\sigma}_f \cdot (\mathbf{p}_\ell \times \mathbf{p}_\nu) \quad (5)$$

for final baryon polarization, would indicate failure of time-reversal invariance. The phase angle ϕ has been measured precisely only in neutron decay (and in ^{19}Ne nuclear beta decay), and the results are consistent with T invariance.

Hyperon nonleptonic decays

The amplitude for a spin-1/2 hyperon decaying into a spin-1/2 baryon and a spin-0 meson may be written in the form

$$M = G_F m_\pi^2 \cdot \overline{B}_f (A - B\gamma_5) B_i \ , \tag{6}$$

where A and B are constants [1]. The transition rate is proportional to

$$R = 1 + \gamma\, \hat{\omega}_f \cdot \hat{\omega}_i + (1-\gamma)(\hat{\omega}_f \cdot \hat{\mathbf{n}})(\hat{\omega}_i \cdot \hat{\mathbf{n}}) + \alpha(\hat{\omega}_f \cdot \hat{\mathbf{n}} + \hat{\omega}_i \cdot \hat{\mathbf{n}}) + \beta \hat{\mathbf{n}} \cdot (\hat{\omega}_f \times \hat{\omega}_i) \ , \tag{7}$$

where $\hat{\mathbf{n}}$ is a unit vector in the direction of the final baryon momentum, and $\hat{\omega}_i$ and $\hat{\omega}_f$ are unit vectors in the directions of the initial and final baryon spins. (The sign of the last term in the above equation was incorrect in our 1988 and 1990 editions.) The parameters α, β, and γ are defined as

$$\alpha = 2\,\mathrm{Re}(s^* p)/(|s|^2 + |p|^2) \ ,$$
$$\beta = 2\,\mathrm{Im}(s^* p)/(|s|^2 + |p|^2) \ ,$$
$$\gamma = (|s|^2 - |p|^2)/(|s|^2 + |p|^2) \ , \tag{8}$$

where $s = A$ and $p = |\mathbf{p}_f| B/(E_f + m_f)$; here E_f and $\mathbf{p}_f$ are the energy and momentum of the final baryon. The parameters α, β, and γ satisfy

$$\alpha^2 + \beta^2 + \gamma^2 = 1 \ . \tag{9}$$

If the hyperon polarization is $\mathbf{P}_Y$, the polarization $\mathbf{P}_B$ of the decay baryons is

$$\mathbf{P}_B = \frac{(\alpha + \mathbf{P}_Y \cdot \hat{\mathbf{n}})\hat{\mathbf{n}} + \beta(\mathbf{P}_Y \times \hat{\mathbf{n}}) + \gamma \hat{\mathbf{n}} \times (\mathbf{P}_Y \times \hat{\mathbf{n}})}{1 + \alpha \mathbf{P}_Y \cdot \hat{\mathbf{n}}} \ . \tag{10}$$

Here $\mathbf{P}_B$ is defined in the rest system of the baryon, obtained by a Lorentz transformation along $\hat{\mathbf{n}}$ from the hyperon rest frame, in which $\hat{\mathbf{n}}$ and $\mathbf{P}_Y$ are defined.

An additional useful parameter ϕ is defined by

$$\beta = (1 - \alpha^2)^{1/2} \sin\phi \ . \tag{11}$$

In the Listings, we compile α and ϕ for each decay, since these quantities are most closely related to experiment and are essentially uncorrelated. When necessary, we have changed the signs of reported values to agree with our sign conventions. In the Baryon Summary Table, we give α, ϕ, and Δ (defined below) with errors, and also give the value of γ without error.

Time-reversal invariance requires, in the absence of final-state interactions, that s and p be relatively real, and therefore that $\beta = 0$. However, for the decays discussed here, the final-state interaction is strong. Thus

$$s = |s|\, e^{i\delta_s} \text{ and } p = |p|\, e^{i\delta_p} \ , \tag{12}$$

where δ_s and δ_p are the pion-baryon s- and p-wave strong interaction phase shifts. We then have

$$\beta = \frac{-2|s|\,|p|}{|s|^2 + |p|^2} \sin(\delta_s - \delta_p) \ . \tag{13}$$

One also defines $\Delta = -\tan^{-1}(\beta/\alpha)$. If T invariance holds, $\Delta = \delta_s - \delta_p$. For $\Lambda \to p\pi^-$ decay, the value of Δ may be compared with the s- and p-wave phase shifts in low-energy $\pi^- p$ scattering, and the results are consistent with T invariance.

See also the note on "Radiative Hyperon Decays" in the Ξ^0 Listings in this *Review*.

N AND Δ RESONANCES

I. Introduction

The excited states of the nucleon have been studied in a large number of formation and production experiments. The conventional (*i.e.,* Breit-Wigner) masses, pole positions, widths, and elasticities of the N and Δ resonances in the Baryon Summary Table come largely from partial-wave analyses of πN total, elastic, and charge-exchange scattering data. Partial-wave analyses have also been performed on much smaller data sets to get $N\eta$, ΛK, and ΣK branching fractions. Other branching fractions come from isobar-model analyses of $\pi N \to N\pi\pi$ data. Finally, many $N\gamma$ branching fractions have been determined from photoproduction experiments (see Sec. III).

Table 1 lists all the N and Δ entries in the Baryon Listings and gives our evaluation of the status of each, both overall and channel by channel. Only the "established" resonances (overall status 3 or 4 stars) appear in the Baryon Summary Table. We generally consider a resonance to be established only if it has been seen in at least two independent analyses of elastic scattering and if the relevant partial-wave amplitudes do not behave erratically or have large errors.

Table 1. The status of the N and Δ resonances. Only those with an overall status of *** or **** are included in the main Baryon Summary Table.

			Status as seen in —

****	Existence is certain, and properties are at least fairly well explored.
***	Existence ranges from very likely to certain, but further confirmation is desirable and/or quantum numbers, branching fractions, *etc.* are not well determined.
**	Evidence of existence is only fair.
*	Evidence of existence is poor.

While no new elastic partial-wave analyses have been published since our last edition, a comprehensive set of resonance parameters has been extracted from a multi-channel analysis of transition amplitudes and data for πN scattering to six

baryon-meson final states [1]. This work has determined both Breit-Wigner and pole parameters for resonances up to about 2 GeV.

The interested reader will find further discussions in the proceedings of two recent conferences [2, 3], and in two older reviews [4, 5].

II. Using the N and Δ listings

Written 2002 by G. Höhler (University of Karlsruhe) and R.L Workman, (George Washington University)

In the inelastic region, a resonance is associated with a cluster of poles on different Riemann sheets. If one of these poles is located near the real axis and far enough from branch points, it will be strongly dominant. If one of the final-state particles itself has a strong decay, it is also necessary to consider branch points in the lower half plane that belong to thresholds for two-particle final states; see for example Refs. 6 and 7.

Our Particle Listings and Summary Tables include pole parameters for the N and Δ resonances. However, the Breit-Wigner parameters are most often quoted and are used in model-based studies of the baryons and associated reaction dynamics. Problems associated with this choice were discussed in our 2000 edition [8]. Here we just point out that the use of Breit-Wigner parameters for complicated structures, such as the N(1440), should be avoided. In this case, the method used in Ref. 7 is suitable for the analysis.

In the search for "missing" quark-model states, indications of new structures occasionally are found. Often these are associated (if possible) with the one- and two-star states listed in Table 1. We caution against this: The status of the one- and two-star states found in the Karlsruhe-Helsinki (KH80) [4] and Carnegie-Mellon/Berkeley (CMB80) [9] fits is now doubtful. Predictions for π^+p spin-rotation parameters from those fits are in significant disagreement with recent ITEP/PNPI measurements [10], whereas the predictions of Ref. 11 are good. This discrepancy has been associated in Ref. 10 with the behavior of a zero trajectory at a "critical point" (see Sec. 2.1.1 of Ref. 4) near a pion lab momentum of 0.8 GeV/c. According to Ref. 10, the effect on the 4-star resonances $\Delta(1905)$ and $\Delta(1950)$ is small, but the effect on the 3-star resonances $\Delta(1920)$ and $\Delta(1930)$ is large. For a study of the approximation made in Ref. 10 and of problems with some higher resonances, the detailed treatment of zero trajectories in Ref. 12 is relevant. This problem should also be considered in any multi-channel analysis that uses the KH80 and CMB80 amplitudes as input.

III. Electromagnetic interactions

Revised 2003 by R.L. Workman (George Washington University)

Nearly all the entries in the Listings concerning electromagnetic properties of the N and Δ resonances are $N\gamma$ couplings. These couplings, the helicity amplitudes $A_{1/2}$ and $A_{3/2}$, have been obtained in partial-wave analyses of single-pion photoproduction, η photoproduction, and Compton scattering. Most photoproduction analyses have taken the existence, masses, and widths of the resonances from the $\pi N \to \pi N$ analyses, and have only determined the $N\gamma$ couplings. This approach is only applicable to resonances with a significant $N\pi$ coupling. A brief description of the various methods of analysis of photoproduction data may be found in our 1992 edition [13].

Our Listings omit a number of analyses that are now obsolete. Most of the older results may be found in our 1982 edition [14]. The errors quoted for the couplings in the Listings are calculated in different ways in different analyses and therefore should be used with care. In general, the systematic differences between the analyses caused by using different parameterization schemes are probably more indicative of the true uncertainties than are the quoted errors.

Probably the most reliable analyses, for most resonances, are ARAI 80, CRAWFORD 80, AWAJI 81, FUJII 81, CRAWFORD 83, and ARNDT 96. There is an update to the Crawford analysis [2]. The errors we give on $N\gamma$ couplings are a combination of the stated statistical errors on the analyses and the systematic differences between them. The analyses are given equal weight, except ARNDT 96 is weighted, rather arbitrarily, by a factor of two because its data set is at least 50% larger than those of the other analyses and contains many new high-quality measurements. The $\Delta(1232)$ and $N(1535)$ are special cases and are discussed in the 2002 *Review* [15].

The Baryon Summary Table gives $N\gamma$ branching fractions for those resonances whose couplings are considered to be reasonably well established. The $N\gamma$ partial width Γ_γ is given in terms of the helicity amplitudes $A_{1/2}$ and $A_{3/2}$ by

$$\Gamma_\gamma = \frac{k^2}{\pi}\frac{2M_N}{(2J+1)M_R}\left[|A_{1/2}|^2 + |A_{3/2}|^2\right] \quad .$$

Here M_N and M_R are the nucleon and resonance masses, J is the resonance spin, and k is the photon c.m. decay momentum.

See our 2002 *Review* for some further discussion [15].

IV. Non-qqq baryon candidates

Revised 2003 by R.L. Workman (George Washington University).

The standard quark-model assignments for baryons are outlined in Sec. 13.3, "Baryons: qqq states." Just as with mesons (see the note on "Non-$q\overline{q}$ mesons"), there have been suggestions that non-qqq baryons might exist, such as hybrid ($qqqg$) baryons, unstable meson-nucleon bound states [16], or pentaquarks ($qqqq\overline{q}$). If hybrid states exist, they will be more difficult to verify than hybrid mesons. Possibilities are listed in Ref. [17] and in our 2000 edition. No hybrid baryon has yet been clearly established. Other unconventional quark configurations include the H dibaryon ($uuddss$). Recent searches for the H dibaryon at BNL [18, 19]. KEK [20], and Fermilab [21] have reported null results.

Recent experiments at a number of labs have reported sharp structures in nK^+ and pK^0 invariant mass distributions, evidence for an S=+1 resonance with a mass of 1540 MeV and a

very narrow width (see our note on "A Possible Exotic Baryon Resonance"). This would be a pentaquark candidate. Evidence for a pentaquark state with hidden strangeness ($qqqs\overline{s}$) has also been reported [22].

Narrow structures continue to be seen in proton-proton and proton-nucleus scattering [23]. However, a number of high-precision searches for such states has found no structure of statistical significance [24]. A clear understanding of this growing set of experiments remains elusive.

Note: Signs of couplings from $\pi N \to N\pi\pi$ analyses were changed in the 1986 edition to agree with the baryon-first convention; the overall phase ambiguity is resolved by choosing a negative sign for the $\Delta(1620)$ S_{31} coupling to $\Delta(1232)\pi$.

$N(1440)$ FOOTNOTES

[1] BAKER 79 finds a coupling of the $N(1440)$ to the $N\eta$ channel near (but slightly below) threshold.

[2] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[3] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[4] ARNDT 95 also finds a second-sheet pole with real part = 1383 MeV, $-2\times$imaginary part = 210 MeV, and residue with modulus 92 MeV and phase = $-54°$.

[5] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[6] ARNDT 91 (Soln SM90) also finds a second-sheet pole with real part = 1413 MeV, $-2\times$ imaginary part = 256 MeV, and residue = $(78-153i)$ MeV.

[7] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

[8] An alternative which cannot be distinguished from this is to have a P_{13} resonance with M = 1530 MeV, Γ = 79 MeV, and elasticity = +0.271.

[9] LONGACRE 77 considers this coupling to be well determined.

[10] WADA 84 is inconsistent with other analyses; see the Note on N and Δ Resonances.

[11] Converted to our conventions using M = 1486 MeV, Γ = 613 MeV from NOELLE 78.

Note: Signs of couplings from $\pi N \rightarrow N\pi\pi$ analyses were changed in the 1986 edition to agree with the baryon-first convention; the overall phase ambiguity is resolved by choosing a negative sign for the $\Delta(1620)$ S_{31} coupling to $\Delta(1232)\pi$.

$N(1520)$ FOOTNOTES

[1] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[2] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[3] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[4] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

[5] LONGACRE 77 considers this coupling to be well determined.

[6] MUKHOPADHYAY 98 uses an effective Lagrangian approach to analyze η photoproduction data. The *ratio* of the $A_{3/2}$ and $A_{1/2}$ amplitudes is determined, with less model dependence than the amplitudes themselves, to be $A_{3/2}/A_{1/2} = -2.5 \pm 0.5 \pm 0.4$.

[7] Converted to our conventions using M = 1528 MeV, Γ = 187 MeV from NOELLE 78.

$N(1535)$ DECAY MODES

The following branching fractions are our estimates, not fits or averages.

	Mode	Fraction (Γ_i/Γ)
Γ_1	$N\pi$	35–55 %
Γ_2	$N\eta$	30–55 %
Γ_3	$N\pi\pi$	1–10 %
Γ_4	$\Delta\pi$	<1 %
Γ_5	$\Delta(1232)\pi$, D-wave	
Γ_6	$N\rho$	<4 %
Γ_7	$N\rho$, S=1/2, S-wave	
Γ_8	$N\rho$, S=3/2, D-wave	
Γ_9	$N(\pi\pi)^{I=0}_{S\text{-wave}}$	<3 %
Γ_{10}	$N(1440)\pi$	<7 %
Γ_{11}	$p\gamma$	0.15–0.35 %
Γ_{12}	$p\gamma$, helicity=1/2	0.15–0.35 %
Γ_{13}	$n\gamma$	0.004–0.29 %
Γ_{14}	$n\gamma$, helicity=1/2	0.004–0.29 %

Note: Signs of couplings from $\pi N \to N\pi\pi$ analyses were changed in the 1986 edition to agree with the baryon-first convention; the overall phase ambiguity is resolved by choosing a negative sign for the $\Delta(1620)$ S_{31} coupling to $\Delta(1232)\pi$.

$N(1535)$ FOOTNOTES

[1] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[2] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[3] KRUSCHE 97 fits with the mass fixed at 1544 MeV.

[4] ARNDT 98 also lists pole residues, which display more model dependence than do the associated pole positions.

[5] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[6] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

[7] The best value ARMSTRONG 99B obtains is $\simeq 0.55$; this assumes S_{11} dominance in the reaction $p(e,\ e'\ p)\ \eta$ at $Q^2 = 4$ (GeV/c)^2.

[8] This STAROSTIN 03 value is an estimate made using simplest assumptions.

[9] BENMERROUCHE 91 uses an effective Lagrangian approach to analyze η photoproduction data.

[10] Converted to our conventions using M = 1548 MeV, Γ = 73 MeV from NOELLE 78.

$N(1650)$ DECAY MODES

The following branching fractions are our estimates, not fits or averages.

	Mode	Fraction (Γ_i/Γ)
Γ_1	$N\pi$	55–90 %
Γ_2	$N\eta$	3–10 %
Γ_3	ΛK	3–11 %
Γ_4	ΣK	
Γ_5	$N\pi\pi$	10–20 %
Γ_6	$\Delta\pi$	1–7 %
Γ_7	$\Delta(1232)\pi$, D-wave	
Γ_8	$N\rho$	4–12 %
Γ_9	$N\rho$, S=1/2, S-wave	
Γ_{10}	$N\rho$, S=3/2, D-wave	
Γ_{11}	$N(\pi\pi)^{I=0}_{S\text{-wave}}$	< 4 %
Γ_{12}	$N(1440)\pi$	< 5 %
Γ_{13}	$p\gamma$	0.04–0.18 %
Γ_{14}	$p\gamma$, helicity=1/2	0.04–0.18 %
Γ_{15}	$n\gamma$	0.003–0.17 %
Γ_{16}	$n\gamma$, helicity=1/2	0.003–0.17 %

Note: Signs of couplings from $\pi N \to N\pi\pi$ analyses were changed in the 1986 edition to agree with the baryon-first convention; the overall phase ambiguity is resolved by choosing a negative sign for the $\Delta(1620)$ S_{31} coupling to $\Delta(1232)\pi$.

$N(1650)$ FOOTNOTES

[1] ARNDT 95 finds two distinct states.

[2] BATINIC 95 finds two distinct states. This second resonance was associated with the $N(2090)$ S_{11}.

[3] The two BAKER 77 entries are from an IPWA using the Barrelet-zero method and from a conventional energy-dependent analysis.

[4] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[5] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[6] ARNDT 98 also lists pole residues, which display more model dependence than do the associated pole positions.

[7] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[8] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
[9] BAKER 79 fixed this coupling during fitting, but the negative sign relative to the $N(1535)$ is well determined.
[10] The overall phase of BAKER 78 couplings has been changed to agree with previous conventions. Superseded by SAXON 80.
[11] The range given for DEANS 75 is from the four best solutions.
[12] LONGACRE 77 considers this coupling to be well determined.

$N(1675)$ DECAY MODES

The following branching fractions are our estimates, not fits or averages.

	Mode	Fraction (Γ_j/Γ)
Γ_1	$N\pi$	40–50 %
Γ_2	$N\eta$	(0.0±1.0) %
Γ_3	ΛK	<1 %
Γ_4	ΣK	
Γ_5	$N\pi\pi$	50–60 %
Γ_6	$\Delta\pi$	50–60 %
Γ_7	$\Delta(1232)\pi$, D-wave	
Γ_8	$\Delta(1232)\pi$, G-wave	
Γ_9	$N\rho$	< 1–3 %
Γ_{10}	$N\rho$, S=1/2, D-wave	
Γ_{11}	$N\rho$, S=3/2, D-wave	
Γ_{12}	$N\rho$, S=3/2, G-wave	
Γ_{13}	$N(\pi\pi)^{I=0}_{S\text{-wave}}$	
Γ_{14}	$p\gamma$	0.004–0.023 %
Γ_{15}	$p\gamma$, helicity=1/2	0.0–0.015 %
Γ_{16}	$p\gamma$, helicity=3/2	0.0–0.011 %
Γ_{17}	$n\gamma$	0.02–0.12 %
Γ_{18}	$n\gamma$, helicity=1/2	0.006–0.046 %
Γ_{19}	$n\gamma$, helicity=3/2	0.01–0.08 %

Note: Signs of couplings from $\pi N \to N\pi\pi$ analyses were changed in the 1986 edition to agree with the baryon-first convention; the overall phase ambiguity is resolved by choosing a negative sign for the $\Delta(1620)$ S_{31} coupling to $\Delta(1232)\pi$.

$N(1675)$ FOOTNOTES

[1] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[2] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[3] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[4] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

[5] SAXON 80 finds the coupling phase is near 90°.

[6] The range given is from the four best solutions. DEANS 75 disagrees with $\pi^+ p \to \Sigma^+ K^+$ data of WINNIK 77 around 1920 MeV.

[7] LONGACRE 77 considers this coupling to be well determined.

[8] A Breit-Wigner fit to the HERNDON 75 IPWA.

Note: Signs of couplings from $\pi N \to N\pi\pi$ analyses were changed in the 1986 edition to agree with the baryon-first convention; the overall phase ambiguity is resolved by choosing a negative sign for the $\Delta(1620)$ S_{31} coupling to $\Delta(1232)\pi$.

$N(1680)$ FOOTNOTES

[1] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[2] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[3] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[4] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

[5] The parametrization used may be double counting.

[6] The range given is from 3 of 4 best solutions; not present in solution 1. DEANS 75 disagrees with $\pi^+ p \rightarrow \Sigma^+ K^+$ data of WINNIK 77 around 1920 MeV.
[7] LONGACRE 77 considers this coupling to be well determined.
[8] A Breit-Wigner fit to the HERNDON 75 IPWA.

$N(1700)$ D_{13}

$I(J^P) = \frac{1}{2}(\frac{3}{2}^-)$ Status: ***

Most of the results published before 1975 are now obsolete and have been omitted. They may be found in our 1982 edition, Physics Letters **111B** (1982).

The various partial-wave analyses do not agree very well.

Note: Signs of couplings from $\pi N \to N\pi\pi$ analyses were changed in the 1986 edition to agree with the baryon-first convention; the overall phase ambiguity is resolved by choosing a negative sign for the $\Delta(1620)$ S_{31} coupling to $\Delta(1232)\pi$.

$N(1700)$ FOOTNOTES

[1] The two BAKER 77 entries are from an IPWA using the Barrelet-zero method and from a conventional energy-dependent analysis.

[2] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[3] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[4] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[5] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

[6] The overall phase of BAKER 78 couplings has been changed to agree with previous conventions.

[7] The range given is from the four best solutions.

$N(1710)$ FOOTNOTES

[1] BATINIC 95 finds a second state with a 6 MeV mass difference.
[2] The two BAKER 77 entries are from an IPWA using the Barrelet-zero method and from a conventional energy-dependent analysis.
[3] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
[4] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
[5] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
[6] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
[7] The overall phase of BAKER 78 couplings has been changed to agree with previous conventions.
[8] The range given for DEANS 75 is from the four best solutions.

$N(1720)$ P_{13}

$I(J^P) = \frac{1}{2}(\frac{3}{2}^+)$ Status: ****

Most of the results published before 1975 are now obsolete and have been omitted. They may be found in our 1982 edition, Physics Letters **111B** (1982).

RIPANI 03, in a study of $ep \to e'p\pi^+\pi^-$, finds some evidence for another P_{13} resonance in this region.

$N(1720)$ FOOTNOTES

[1] The two BAKER 77 entries are from an IPWA using the Barrelet-zero method and from a conventional energy-dependent analysis.

[2] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[3] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[4] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[5] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

[6] The overall phase of BAKER 78 couplings has been changed to agree with previous conventions.

[7] The range given is from the four best solutions. DEANS 75 disagrees with $\pi^+ p \to \Sigma^+ K^+$ data of WINNIK 77 around 1920 MeV.

$I(J^P) = \frac{1}{2}(\frac{3}{2}^-)$ Status: $**$

OMITTED FROM SUMMARY TABLE

There is some evidence for two resonances in this wave between 1800 and 2200 MeV (see CUTKOSKY 80). However, the solution of HOEHLER 79 is quite different.

Most of the results published before 1975 are now obsolete and have been omitted. They may be found in our 1982 edition, Physics Letters **111B** (1982).

$N(2080)$ FOOTNOTES

[1] CUTKOSKY 80 finds a lower mass D_{13} resonance, as well as one in this region. Both are listed here.

[2] The range given for DEANS 75 is from the four best solutions. Disagrees with $\pi^+ p \to \Sigma^+ K^+$ data of WINNIK 77 around 1920 MeV.

$N(2090)$ FOOTNOTES

[1] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

$N(2190)$ FOOTNOTES

[1] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
[2] The range given for DEANS 75 is from the four best solutions. Disagrees with $\pi^+ p \to \Sigma^+ K^+$ data of WINNIK 77 around 1920 MeV.

$N(\sim 3000$ Region) Partial-Wave Analyses

OMITTED FROM SUMMARY TABLE

We list here miscellaneous high-mass candidates for isospin-1/2 resonances found in partial-wave analyses.

Our 1982 edition had an $N(3245)$, an $N(3690)$, and an $N(3755)$, each a narrow peak seen in a production experiment. Since nothing has been heard from them since the 1960's, we declare them to be dead. There was also an $N(3030)$, deduced from total cross-section and 180° elastic cross-section measurements; it is the KOCH 80 $L_{1,15}$ state below.

Δ(1232) MAGNETIC MOMENTS

Δ(1232)++ MAGNETIC MOMENT

The values are extracted from UCLA and SIN data on $\pi^+ p$ bremsstrahlung using a variety of different theoretical approximations and methods. Our estimate is *only* a rough guess of the range we expect the moment to lie within.

$2.7^{+1.0}_{-1.3} \pm 1.5 \pm 3$	[2] KOTULLA	02	$\gamma p \to p\pi^0\gamma'$

[2] The second error is systematic, the third is an estimate of theoretical uncertainties.

Δ(1232) FOOTNOTES

[3] Using $\pi^\pm d$ as well, PEDRONI 78 determine $(M^- - M^{++}) + (M^0 - M^+)/3 = 4.6 \pm 0.2$ MeV.

[4] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[5] This VASAN 76B value is from fits to the coulomb-barrier-corrected CARTER 73 phase shift.

[6] This VASAN 76B value is from fits to the CARTER 73 nuclear phase shift without coulomb barrier corrections.

[7] This ARNDT 95 value is in error, as pointed out by HOHLER 01. The corrected value is in line with the ARNDT 91 value (R.A. Arndt, private communication).

[8] Converted to our conventions using $M = 1232$ MeV, $\Gamma = 110$ MeV from NOELLE 78.

[9] This ARNDT 97 value is very sensitive to the database being fitted. The result is from a fit to the full pion photoproduction database, apart from the BLANPIED 97 cross-section measurements.

Δ(1600) P_{33}

$I(J^P) = \frac{3}{2}(\frac{3}{2}^+)$ Status: ***

Most of the results published before 1975 are now obsolete and have been omitted. They may be found in our 1982 edition, Physics Letters **111B** (1982).

The various analyses are not in good agreement.

Δ(1600) FOOTNOTES

[1] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[2] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[3] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[4] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

[5] The range given is from the four best solutions. DEANS 75 disagrees with $\pi^+ p \to \Sigma^+ K^+$ data of WINNIK 77 around 1920 MeV.

[6] LONGACRE 77 considers this coupling to be well determined.

[7] WADA 84 is inconsistent with other analyses — see the Note on N and Δ Resonances.

$\Delta(1620)$ DECAY MODES

The following branching fractions are our estimates, not fits or averages.

	Mode	Fraction (Γ_j/Γ)
Γ_1	$N\pi$	20–30 %
Γ_2	$N\pi\pi$	70–80 %
Γ_3	$\Delta\pi$	30–60 %
Γ_4	$\Delta(1232)\pi$, D-wave	
Γ_5	$N\rho$	7–25 %
Γ_6	$N\rho$, S=1/2, S-wave	
Γ_7	$N\rho$, S=3/2, D-wave	
Γ_8	$N(1440)\pi$	
Γ_9	$N\gamma$	0.004–0.044 %
Γ_{10}	$N\gamma$, helicity=1/2	0.004–0.044 %

$\Delta(1620)$ BRANCHING RATIOS

Note: Signs of couplings from $\pi N \to N\pi\pi$ analyses were changed in the 1986 edition to agree with the baryon-first convention; the overall phase ambiguity is resolved by choosing a negative sign for the $\Delta(1620)$ S_{31} coupling to $\Delta(1232)\pi$.
