$\Delta(1620)$ FOOTNOTES

[1] CHEW 80 reports two S_{31} resonances at somewhat higher masses than other analyses. Problems with this analysis are discussed in section 2.1.11 of HOEHLER 83.

[2] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[3] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[4] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[5] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

[6] LONGACRE 77 considers this coupling to be well determined.

Δ(1700) FOOTNOTES

[1] Problems with CHEW 80 are discussed in section 2.1.11 of HOEHLER 83.
[2] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
[3] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
[4] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
[5] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
[6] The range given is from the four best solutions. DEANS 75 disagrees with $\pi^+ p \to \Sigma^+ K^+$ data of WINNIK 77 around 1920 MeV.
[7] LONGACRE 77 considers this coupling to be well determined.

$\Delta(1900)$ FOOTNOTES

[1] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[2] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

[3] The value given is from solution 1; the resonance is not present in solutions 2, 3, or 4.

Δ(1905) FOOTNOTES

[1] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[2] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of *N* and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[3] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

[4] The range given for DEANS 75 is from the four best solutions.

[5] A Breit-Wigner fit to the HERNDON 75 IPWA.

[6] A Breit-Wigner fit to the NOVOSELLER 78B IPWA.

[7] A Breit-Wigner fit to the NOVOSELLER 78B IPWA; the phase is near 90°.

Note: Signs of couplings from $\pi N \to N\pi\pi$ analyses were changed in the 1986 edition to agree with the baryon-first convention; the overall phase ambiguity is resolved by choosing a negative sign for the $\Delta(1620)$ S_{31} coupling to $\Delta(1232)\pi$.

Δ(1910) FOOTNOTES

[1] CHEW 80 reports four resonances in the P_{31} wave — see also the Δ(1750). Problems with this analysis are discussed in section 2.1.11 of HOEHLER 83.

[2] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[3] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[4] The range given for DEANS 75 is from the four best solutions.

[5] Evidence for this coupling is weak; see NOVOSELLER 78. This coupling assumes the mass is near 1820 MeV.

Δ(1920) FOOTNOTES

[1] CHEW 80 reports two P_{33} resonances in this mass region. Problems with this analysis are discussed in section 2.1.11 of HOEHLER 83.
[2] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
[3] The range given for DEANS 75 is from the four best solutions.
[4] A Breit-Wigner fit to the HERNDON 75 IPWA; the phase is near −90°.
[5] A Breit-Wigner fit to the NOVOSELLER 78B IPWA; the phase is near −90°.

Δ(1950) DECAY MODES

The following branching fractions are our estimates, not fits or averages.

	Mode	Fraction (Γ_i/Γ)
Γ_1	$N\pi$	35–40 %
Γ_2	ΣK	
Γ_3	$N\pi\pi$	
Γ_4	$\Delta\pi$	20–30 %
Γ_5	$\Delta(1232)\pi$, F-wave	
Γ_6	$\Delta(1232)\pi$, H-wave	
Γ_7	$N\rho$	<10 %
Γ_8	$N\rho$, S=1/2, F-wave	
Γ_9	$N\rho$, S=3/2, F-wave	
Γ_{10}	$N\gamma$	0.08–0.13 %
Γ_{11}	$N\gamma$, helicity=1/2	0.03–0.055 %
Γ_{12}	$N\gamma$, helicity=3/2	0.05–0.075 %

Δ(1950) FOOTNOTES

[1] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
[2] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
[3] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
[4] The range given is from the four best solutions. DEANS 75 disagrees with $\pi^+ p \to \Sigma^+ K^+$ data of WINNIK 77 around 1920 MeV.
[5] A Breit-Wigner fit to the HERNDON 75 IPWA; the phase is near −60°.
[6] A Breit-Wigner fit to the NOVOSELLER 78B IPWA; the phase is near −60°.
[7] A Breit-Wigner fit to the HERNDON 75 IPWA; the phase is near 120°.
[8] A Breit-Wigner fit to the NOVOSELLER 78B IPWA; the phase is near 120°.

$\Delta(\sim 3000$ Region) Partial-Wave Analyses

OMITTED FROM SUMMARY TABLE

We list here miscellaneous high-mass candidates for isospin-3/2 resonances found in partial-wave analyses.

Our 1982 edition also had a $\Delta(2850)$ and a $\Delta(3230)$. The evidence for them was deduced from total cross-section and 180° elastic cross-section measurements. The $\Delta(2850)$ has been resolved into the $\Delta(2750)$ $I_{3,13}$ and $\Delta(2950)$ $K_{3,15}$. The $\Delta(3230)$ is perhaps related to the $K_{3,13}$ of HENDRY 78 and to the $L_{3,17}$ of KOCH 80.

A POSSIBLE EXOTIC BARYON RESONANCE

Written November 2003 by G. Trilling (LBNL).

I. Introduction

The well-established baryon states can be understood as combinations of three valence quarks. In this discussion, we confine ourselves to baryon states constructed from combinations of u, d, and s quarks. The three-quark combinations are members of SU(3) singlets, octets, and decuplets. Baryon states that cannot be constructed with triplets of u, d, and s quarks are called exotic.

Do there exist in nature baryon states constructed from more complicated quark configurations? The simplest might consist of four quarks plus an antiquark. In a 1997 paper [1], Diakonov *et al.* proposed, on the basis of a chiral soliton model, the existence of a low-mass anti-decuplet of such baryons, with spin 1/2 and even parity, and with specific estimates for the masses and widths. Figure 1, from their paper, shows this proposed anti-decuplet. The baryons at the three corners of the triangle are exotic: their isospin and strangeness cannot be obtained by any triplet combination of u, d, and s quarks. The other baryons of the anti-decuplet are made up of combinations such as, for example, $uudd\overline{d}$ and $uuds\overline{s}$ (relevant to the charged $N(1710)$ in Fig. 1). These two combinations have the same isospin and strangeness as uud, and the corresponding baryons are therefore not exotic. Diakonov *et al.* estimated the masses and widths of the four isospin multiplets in the anti-decuplet of Fig. 1. They assumed equal mass spacings between multiplets, with a calculated spacing of 180 MeV. Associating the $S = 0$ isospin doublet with the $N(1710)$, an $I = J = 1/2$, P-wave πN resonance listed in our Tables, they predicted a mass of 1530 MeV for the $S = +1$ exotic Z^+ isosinglet. They also estimated its total decay width to be 15 MeV or less.

Before 2003, there was no evidence for a narrow $S = +1$ baryon resonance, but that situation has now changed. In 2003, several groups searched old or new data for evidence of a K^+n or K^0p resonance in the neighborhood of the predicted 1530 MeV and reported positive results. On the other hand, attempts to find this exotic state in other fairly extensive older published data have so far yielded no supporting evidence. We first consider the new positive results, and then review some of the relevant older information. One point of nomenclature: the Z^+ is now universally called the Θ^+.

II. Recent results

We discuss the results from seven different experiments. Five are photo- or electroproduction experiments using carbon, deuterium, or hydrogen targets, one is a K^+n charge-exchange experiment in a liquid-xenon bubble chamber, and one involves a compilation of neutrino bubble-chamber data with hydrogen, deuterium, and neon fills. As an example, we show in Fig. 2 the nK^+ mass spectrum from the first of two CLAS photoproduction experiments discussed below [2]. The structure at 1540 MeV is interpreted as a possible Θ^+ signal with a significance of 5.2 σ.

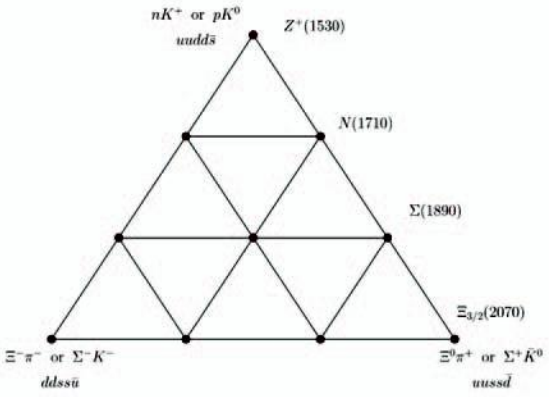

Figure 1: Proposed anti-decuplet of baryons (from [1]).

The LEPS experiment — The LEPS experiment [3] was carried out at the Laser-Electron-Photon facility at the Spring-8 Synchrotron Radiation Facility in Japan during 2000–2001. A photon beam with tagged energies between 1.5 and 2.4 GeV was incident on a scintillator target; for the Θ^+ search, the reaction $\gamma n \to nK^+K^-$, with carbon from the scintillator as the neutron target, was identified and measured in the LEPS spectrometer. The goal was to search for a nK^+ mass enhancement. Cuts were made to remove a large number of $\phi \to K^+K^-$ decays and possible backgrounds from $\gamma p \to pK^+K^-$ in the same carbon target. Corrections were made for the Fermi momentum of the target nucleon, relevant to the reconstruction since the final-state neutron is not detected. After cuts, the final sample consists of 109 events. There is a peak at 1540 MeV, consisting of 19 events above a background of 17. The significance is claimed to be 4.6 σ, the mass 1540 ± 10 MeV, and the width less than 25 MeV at 90% confidence.

The DIANA experiment — The DIANA experiment [4], run in 1986, was a xenon bubble-chamber exposure to a K^+ beam. The K^+ momentum at the bubble-chamber entry was 750 MeV/c, decreasing through ionization loss all the way to rest at the back of the chamber. Only those interactions produced by K^+ of momenta below 550 MeV/c were considered in the analysis, which focused on charge-exchange events, $K^+\mathrm{Xe} \to K^0_S pX$, with the K^0_S decaying into $\pi^+\pi^-$. After cuts to remove

See key on page 323

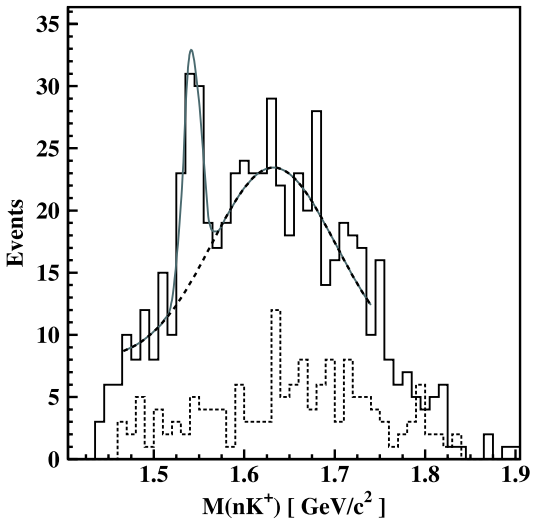

Figure 2: Invariant nK^+ mass spectrum from the reaction $\gamma d \to K^+K^-pn$ after cuts. The dotted histogram shows events associated with $\Lambda(1520) \to K^-p$ production (from [2]).

low-momentum protons and K^0_S, and cuts on K^0_S and proton directions (said to reduce the effects of rescatterings in nuclear matter), a sharp peak in the pK^0_S mass spectrum at 1539 ± 2 MeV, consisting of a signal of 29 events over a background of 44 events, was observed. The quoted statistical significance is 4.4 σ, and the width upper limit is 9 MeV.

The CLAS experiments — The first of the CLAS experiments [2], run in 1999 at Jefferson Lab, studied the nK^+ mass spectrum from the reaction $\gamma d \to npK^+K^-$, produced by a tagged photon beam of energies between 1.5 and 2.9 GeV. The events of interest are really $\gamma n \to nK^+K^-$, but reconstruction requires a detectable proton; hence only events with a rescattering that changes the spectator into a detectable proton are useful. With removal of $\phi \to K^+K^-$ and $\Lambda(1520) \to pK^-$ events, and an imposed upper limit of 1 GeV/c on the K^+ momentum, the spectrum shown in Fig. 2, with a signal of 43 events over a background of about 54 events, is observed. The mass is 1542 ± 5 MeV, the quoted significance is 5.2 σ, and the observed width of 21 MeV is consistent with the instrumental resolution.

Another CLAS experiment [5] studied the reaction $\gamma p \to n\pi^+K^+K^-$, a four-body final state, with photons of energies between 3 and 5.5 GeV. After a ϕ mass cut, the nK^+ mass distribution for 14,000 events shows no significant structure. To enrich the sample, angular requirements that select events with forward π^+ and backward K^+ are imposed. These cuts remove about 95% of the events, leaving a peak in the nK^+ mass at 1555 ± 10 MeV. The fit yields a signal of 41 events over a background of about 35 events, with a quoted significance of 7.8 σ. The observed width of 26 MeV is consistent with the resolution.

The SAPHIR experiment — The 1997–1998 data from the SAPHIR experiment [6], run at the ELSA facility in Bonn, allow study of the reaction $\gamma p \to nK^+K^0_S$, with an incident tagged photon beam with energy between 0.9 and 2.6 GeV. To enhance the Θ^+ signal, a requirement that $\cos\theta_{\rm cm} > 0.5$, where $\theta_{\rm cm}$ is the angle between the beam and the K^0_S in the center of mass, is imposed. A signal of about 55 events over a background of about 56 is observed in the nK^+ mass spectrum at a mass of $1540 \pm 4 \pm 2$ MeV. The quoted significance is 4.8 σ, and the width is less than 25 MeV. Because there is no significant signal in the pK^+ spectrum observed in a separate experiment to study $\gamma p \to pK^+K^-$, the authors conclude that the Θ^+ must have $I = 0$.

A compendium of neutrino experiments — Asratyan *et al.* [7] have analyzed a database of some 120,000 ν and $\overline{\nu}$ charged-current events from the BEBC (CERN) and 15-foot (Fermilab) bubble chambers; the fills were hydrogen, deuterium, or neon. Some of the runs had mean incident energies of about 40 GeV and others about 110 GeV. The authors looked for final states with a proton (momentum between 300 and 900 MeV/c), and a K^0_S decay, both originating from the same vertex. The goal was to search for evidence of the Θ^+ in the pK^0_S mass spectra. A signal consisting of an excess of about 27 events over a background of about 8 events, at 1533 ± 5 MeV, was observed in the combined neon and deuterium data. The quoted significance is 6.7 σ, and the width is less than 20 MeV. There is one concern here: the K^0_S can have $S = +1$ or -1, and there are numerous $S = -1$ baryon resonances. The authors argue that, since there is no established $S = -1$, $I = 1$ narrow resonance near 1530 MeV, the observed structure must be taken as evidence for the Θ^+.

The HERMES experiment — In the HERMES experiment [8], a 27.6 GeV positron beam from the HERA storage ring is incident on a deuterium target in a search for Θ^+ in quasi-real inclusive photoproduction. The analysis selects final states with a proton and $K^0_S \to \pi^+\pi^-$ decay. In the resulting pK^0_S mass spectrum, an enhancement at a mass of $1528 \pm 2.6 \pm 2.1$ MeV is observed. Depending on the background model, the significance is said to be 4-to-6 σ and the width may be larger than expected from just the measurement uncertainty of 4.3-to-6.2 MeV (one standard deviation).

III. Information based on earlier data

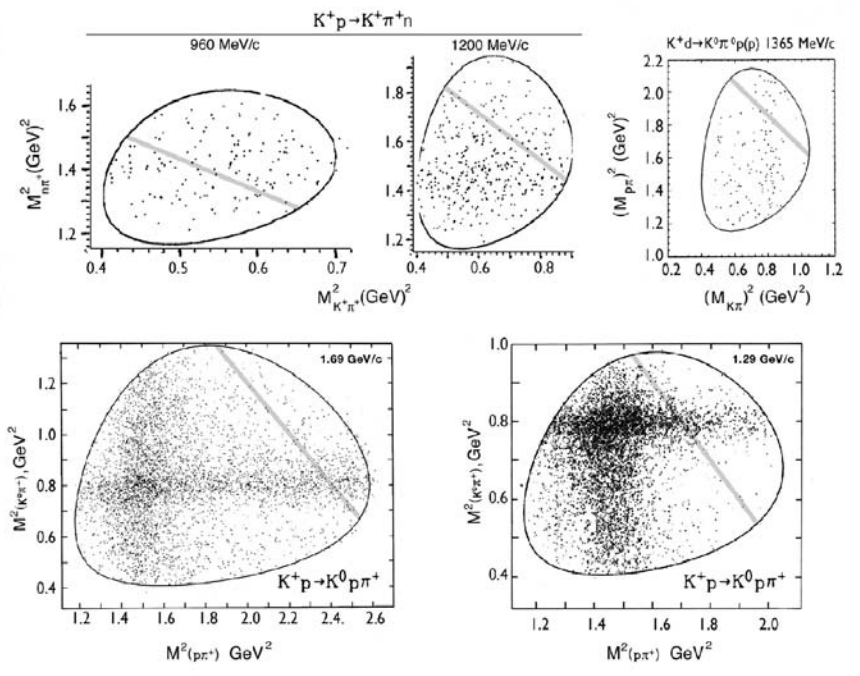
There are a number of old experiments that may be relevant to the search for a Θ^+. We consider three sets of experiments:

(1) Studies of K^+p and K^+d interactions leading to $KN\pi$ final states. One looks for an enhancement in nK^+ and pK^0 mass distributions.

(2) Studies of $\pi^- p$ interactions leading to $K\overline{K}N$ final states, again looking for structure in the KN mass distributions.

(3) Measurements of $K^+ d$ total and charge-exchange cross sections as functions of incident momentum, looking for a cross section peak in the neighborhood of 440 MeV/c.

The Berthon *et al.* pK^0 mass spectra [12] show no indication of structure near 1540 MeV for incident momenta of 1210, 1290, 1380 MeV/c, but there is just a hint at 1690 MeV/c. Inspection of the corresponding Dalitz plot, however (see Fig. 3), indicates that any small population excess is likely



Dalitz plots for $K^+N \to KN\pi$ reactions studied in hydrogen and deuterium bubble chambers. References, going clockwise starting at upper left, are [9], [9], [13], [12] and [12]. The diagonal lines show where one would expect to see the $\Theta(1540)^+$.

K^+p and $K^+d \to KN\pi$ — One might expect that an $S = +1$ initial state would increase the likelihood of producing an $S = +1$ resonance in the final state. Published results for the reactions $K^+p \to pK^0\pi^+$, $pK^+\pi^0$, and $nK^+\pi^+$, studied in bubble chambers at incident momenta of 960, 1200, 1210, 1290, 1360, 1380, 1520, 1585, 1690, and 2650 MeV/c [9–12], have been examined with some care. In most cases, only Dalitz plots are available, but Berthon *et al.* [12] also supplies pK^0_S mass spectra with very substantial statistics. In these final states, the $K^*(892)$ and $\Delta(1232)$ dominate, and most features of the KN spectra are simply reflections of these resonances. Study of all the available Dalitz plots, especially away from the known resonance bands, shows no indication of a population increase near a pK^0 or nK^+ mass of 1540 MeV. Figure 3 shows some representative Dalitz plots, with the diagonal lines corresponding to a 1540 MeV KN resonance. For a strongly decaying spin-1/2 state, the distribution of points along the lines should be uniform.

related to overlap with the K^* resonance band. Similarly, the $K^+d \to KN\pi(N)$ Dalitz plots (see Fig. 3) from Hirata *et al.* [13] are also dominated by the same known resonance bands.

It is important to note that these bubble-chamber data have no acceptance issue, and that they have not been subjected to any cuts, unlike the claimed signal populations, where cuts have been made that enhance the Θ^+ signal relative to background.

$\pi^- p \to nK^+K^-$ and $pK^0_S K^-$ — Dahl at al. [14] used the Berkeley 72-in hydrogen bubble chamber to study the reactions $\pi^- p \to nK^+K^-$ and $\pi^- p \to pK^-K^0_S$ at momenta from 1.5 to 4.2 GeV/c. Their paper provides the relevant nK^+ and pK^0_S mass spectra, as well as Dalitz plots for three momentum groupings: 1.6–2.3, 2.9–3.3, and 3.8–4.2 GeV/c. Of the six relevant mass spectra, only one, nK^+ at 3.8–4.2 GeV/c, has the slightest hint of structure at low mass, but that structure is actually centered at about 1600 MeV with a width of roughly

200 MeV. There is simply no evidence in these data for a narrow KN resonance at 1540 MeV.

K^+d cross section data — An $I = 0$ KN resonance should manifest itself through increases in the K^+n charge-exchange and total cross sections at the resonance cm energy near 1540 MeV, corresponding for a neutron at rest to an incident K^+ momentum of 442 MeV/c. Since free-neutron targets are not available, K^+d cross-section measurements are required, and proper account must be taken of the Fermi momentum of the bound neutron. The distribution of the Fermi momentum in deuterium peaks near 50 MeV/c, and for a fixed incident K^+ momentum leads to a cm energy distribution with a full width of about 30 MeV. This number is, as shown below, much larger than any reasonable estimate of the Θ^+ width, and also is larger than the typical spread of incident momentum at any measurement point.

It is straightforward to calculate the resonance cross section averaged over the Fermi momentum distribution, as determined by the deuteron wave function. The result can be written as $\sigma_R = AB_iB_f\Gamma$, where B_i and B_f are the initial and final Θ^+ branching ratios relevant to the reaction under study, and Γ is the full width. The coefficient A is the product of several factors, including the result of the Fermi-motion averaging process. For an incident K^+ momentum close to the resonant value for a stationary neutron target (442 MeV/c), and for a Θ^+ having spin 1/2 and isospin 0, the value of A is 3.6 mb/MeV [15].

We first apply this result to K^+d charge exchange, $K^+d \to K^0pp$, using the measurements from Slater *et al.* [16] at incident momenta of 376 and 530 MeV/c, and Damerell *et al.* [17] at 434, 526, and 604 MeV/c. The 434 MeV/c measurement is close to the resonance value, and the others are sufficiently distant that, even with the Fermi smearing, their resonance contributions are small. We estimate the resonance part of the 434-MeV/c cross section by subtracting from it a background estimated from interpolations and extrapolations of the cross sections at the other momenta. These subtractions yield numbers smaller than the estimated errors of 0.3 mb. There is therefore no evidence for a significant resonant contribution, and we estimate a conservative upper limit for σ_R of 1 mb. Here $B_i = B_f = 1/2$ in the above formula, and we deduce an upper limit for Γ of 1.1 MeV.

A similar analysis can be applied to the K^+d total cross section, using the data of Bowen *et al.* [18] at 366, 440, and 506 MeV/c. The 440 MeV/c point is very close to the resonance value, and the other two points are sufficiently distant to avoid the inclusion of resonance contributions arising from Fermi smearing. Subtraction of a linearly interpolated background cross section from the measured value at 440 MeV/c leads to an excess of 0.6 ± 0.3 mb. The fact that this difference deviates from zero should not be taken as evidence for the Θ^+: it can simply reflect deviation from linearity in the momentum dependence of the cross section. We take 1.5 mb as a conservative upper limit to the resonance cross section. Here B_i=1/2 and B_f =1, and the upper limit on Γ is 0.8 MeV.

Finally, we consider the $I = 0$ KN total cross sections reported by Bowen *et al.* [18] and Carroll *et al.* [19] at 440 MeV/c, and take the even more conservative approach of considering the full cross section at that momentum as resonant. The Carroll and Bowen measurements disagree by about 3 mb, and we use Carroll's larger value of 13 mb. With $B_i = B_f = 1$, the upper limit for Γ is 3.6 MeV.

These width limits are predicated on the Θ^+ mass being in the range of 1533–1543 MeV, corresponding closely to incident momenta at which the K^+d charge-exchange and total cross sections have been measured. For masses of 1528 or 1548 MeV, the upper limits would increase by a factor of 1.6.

IV. Width estimate from xenon experiment

The results of the DIANA xenon charge-exchange experiment [4] have been analyzed by Cahn and Trilling [15] on the assumption that, near the resonance, one is observing charge exchange on a single nucleon. Associating the observed signal and background populations with resonant and non-resonant charge-exchange cross sections, they deduce a Θ^+ width of 0.9 ± 0.3 MeV, where the quoted error is statistical. The systematic uncertainty is difficult to evaluate.

V. Results from partial-wave analysis

Motivated by the newly reported results, Arndt *et al.* [20] have recently reanalyzed K^+N scattering data in the 1540 MeV cm energy region. They have considered possible structure not only in the P_{01} partial wave, but also in other S, P, and D waves. An immediate result was that the addition of resonances of widths above 5 MeV resulted in an enormous increase in the χ^2 of their fit to data. Indeed, they found no χ^2 improvement in their fit from the addition of resonances in S, P, or D waves unless the inserted structures had widths of 1 MeV or less. They conclude that Θ^+ widths larger than a few MeV are excluded, but that the existence of a Θ^+ in the P_{01} state with a width of 1 MeV or less is possible. These results are stronger than, although consistent with, a 6-MeV upper limit given by Nussinov [21] and a 5-MeV limit by Haidenbauer and Krein [22], and are consistent with the limits quoted in Secs. III and IV above.

VI. Comments on all these results

What can we conclude from these various results and observations? One general principle should apply: For claims of major new discoveries, the burden of proof is greater than for research results that fall within the boundaries of what is already established. Has this burden been met well enough to claim the discovery of an exotic baryon resonance?

Measured in terms of claimed numbers of standard deviations, the results are impressive. In some cases [5, 6, 7], inspection of the published plots suggests that the backgrounds may be somewhat underestimated (background fits seem to

be normalized below the observed backgrounds), reducing perhaps the real significance of the results. Nevertheless, there are substantial indications that something interesting is being observed. However, that something seems to behave rather differently from the known non-exotic resonances. As one example, the $\Lambda(1520)$ decays by D-wave to $\overline{K}N$ with a partial width of 7.2 MeV, much larger than the upper limits based on measured cross sections and partial-wave analyses for the presumed P-wave $\Theta(1540)^+$.

There are some further concerns about the new evidence for the Θ^+. In most cases, the signal does not appear in a significant way until various cuts are made, often reducing the data sample by a large factor. Because all but the xenon and neutrino experiments involve spectrometers of finite acceptance, it is difficult for the reader of these papers to know what role kinematics and reflections from other resonances may have played in determining the results, especially since the cuts were likely chosen to optimize observed signal to background.

One of the most powerful tools for understanding resonances in three-body final states has been the use of Dalitz plots to study correlations and reflections, yet there are no published Dalitz plots in any of the new papers that involve three-body final states [2, 3, 6]. The possible importance of reflections has been emphasized in a recent paper by Dzierba *et al.* [23].

In three of the papers, the Θ^+ production is from a nucleus (carbon, xenon, or neon): the decay products may be created inside the nucleus, and may further interact before leaving the nucleus, raising some uncertainties about the interpretation of the final state. In short, most of the new papers are relatively brief, and yet, given the potential importance of the results, the work cries for more complete description and discussion.

There is the further problem that there seems to be no evidence for the Θ^+ in the rather extensive existing K^+N charge-exchange and total cross section data, in the $KN\pi$ and $K\overline{K}N$ final states produced by incident kaons and pions over a range of energies, and in the results of K^+N partial wave analyses. All the observations may be consistent with a Θ^+ having a width of 1 MeV or less, but then there are two further questions: Why the very small width for a strong decay, and why is the very narrow Θ^+ so readily produced in photoproduction experiments?

There is one other tantalizing piece of information. Alt *et al.* [24] have recently claimed to see, at the 4 σ level, another exotic baryon, an $S = -2$, $Q = -2$ $ddss\bar{u}$ state (see the lower left corner of Fig. 1) decaying into $\Xi^-\pi^-$ with a mass of 1862 ± 2 MeV and a width of less than 18 MeV. This mass agrees with neither the Diakonov *et al.* prediction of 2070 MeV [1] nor a later prediction of 1750 MeV from Jaffe and Wilczek [25]. Nevertheless, this observation is additional support for the existence of exotic baryons.

VII. Future Needs

What experiments do we need to establish fully the Θ^+, recognizing the fact that its width may be very small? One can suggest two experiments:

(1) Confirmation with high statistics, much improved effective mass resolution, and excellent particle identification, of the photoproduction results, through study of such reactions as $\gamma p \to nK^+K^0_S$, $\gamma n \to pK^0_SK^-$, and $\gamma n \to nK^+K^-$.

(2) Measurement in the 400–500 MeV/c incident momentum range of the $K^+d \to K^0_Sp(p)$ charge-exchange cross section as a function of the final-state K^0_Sp mass. This requires measurement of the K^0_S decay and reconstruction of the K^0_Sp mass with the best possible resolution, in order to demonstrate resonant behavior undiluted by target Fermi motion or beam-momentum spread.

$\Theta(1540)^+$ MASS

As is done through the *Review*, papers are listed by year, with the latest year first, and within each year they are listed alphabetically. NAKANO 03 was the earliest paper.

It is difficult to deny a status of three stars and a place in the Summary Tables for a state that six experiments claim to have seen. Nevertheless, as discussed in the above note, we believe it reasonable to have some reservations about the existence of this state on the basis of the present evidence.

$\Theta(1540)^+$ FOOTNOTES

[1] ASRATYAN 04 analyzes old BEBC and 15-ft bubble-chamber data and estimates a peak of 27 $K^0 p$ events (mostly from $\nu, \overline{\nu}$ in Ne) above a background of 8 events and claims a statistical significance of 6.7 standard deviations.

[2] KUBAROVSKY 04 estimates a peak of 41 $K^+ n$ events and claims a statistical significance of 7.8 ± 1.0 standard deviations.

[3] BARMIN 03 estimates a peak of 29 $K^0 p$ events above a background of 44 events and claims a statistical significance of 4.4 standard deviations.

[4] BARTH 03 estimates a peak of 63 ± 13 $K^+ n$ events and claims a significance of 4.8 standard deviations.

[5] NAKANO 03 estimates a peak of 19.0 ± 2.8 $K^+ n$ events above a background of 17.0 ± 2.8 events and claims a significance of $4.6^{+1.2}_{-1.0}$ standard deviations.

[6] STEPANYAN 03 estimates a peak of 43 $K^+ n$ events above a background of 54 events and claims a statistical significance of 5.2 ± 0.5 standard deviations.

[7] CAHN 04 uses the integrated $K^+ n \to K^0 p$ cross section from the DIANA experiment in xenon (BARMIN 03); some assumptions are needed. Other estimates, based on measured $K^+ d$ cross sections, give upper limits in the 1–4 MeV range.

[8] ARNDT 03 introduces a test resonance in various partial waves in a reanalysis of $K^+ N$ elastic-scattering data and finds that a width of more than an MeV or so would greatly increase the χ^2 of the fit.

VALUE (MeV)	CL%	DOCUMENT ID		TECN	COMMENT
<18	90	[1] ALT	04	NA49	pp, $\sqrt{s} = 17.2$ GeV

[1] ALT 04 estimates a peak of 38 $\Xi^- \pi^-$ events above a background of 43 events and claims a significance of 4.2 standard deviations. Combining $\Xi^- \pi^-$, $\Xi^- \pi^+$, $\overline{\Xi}^+ \pi^+$, and $\overline{\Xi}^+ \pi^-$ events, ALT 04 estimates a peak of 69 over a background of 75, for 5.8 σ. However, when the number of bins searched in is taken into account, the significance then falls to 4.2 σ.

BARYON MAGNETIC MOMENTS

Written 1994 by C.G. Wohl (LBNL).

The figure below shows the measured magnetic moments of the stable baryons. It also shows the predictions of the simplest quark model, using the measured p, n, and Λ moments as input. In this model, the moments are [1]

$$\mu_p = (4\mu_u - \mu_d)/3 \qquad \mu_n = (4\mu_d - \mu_u)/3$$
$$\mu_{\Sigma^+} = (4\mu_u - \mu_s)/3 \qquad \mu_{\Sigma^-} = (4\mu_d - \mu_s)/3$$
$$\mu_{\Xi^0} = (4\mu_s - \mu_u)/3 \qquad \mu_{\Xi^-} = (4\mu_s - \mu_d)/3$$
$$\mu_\Lambda = \mu_s \qquad \mu_{\Sigma^0} = (2\mu_u + 2\mu_d - \mu_s)/3$$
$$\mu_{\Omega^-} = 3\mu_s$$

and the $\Sigma^0 \to \Lambda$ transition moment is

$$\mu_{\Sigma^0\Lambda} = (\mu_d - \mu_u)/\sqrt{3}\ .$$

The quark moments that result from this model are $\mu_u = +1.852\,\mu_N$, $\mu_d = -0.972\,\mu_N$, and $\mu_s = -0.613\,\mu_N$. The corresponding effective quark masses, taking the quarks to be Dirac point particles, where $\mu = q\hbar/2m$, are 338, 322, and 510 MeV. As the figure shows, the model gives a good first approximation to the experimental moments. For efforts to make a better model, we refer to the literature [2].

[a] See the Listings below for the pion momentum range used in this measurement.

CONSTRAINED FIT INFORMATION

An overall fit to 5 branching ratios uses 20 measurements and one constraint to determine 5 parameters. The overall fit has a $\chi^2 = 10.5$ for 16 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

[10] CHAUVAT 85 actually gives $\alpha_+(\overline{\Lambda})/\alpha_-(\Lambda) = -1.04 \pm 0.29$. Assumes polarization is same in $\overline{p}p \to \overline{\Lambda}X$ and $pp \to \Lambda X$. Tests of this assumption, based on *C*-invariance and fragmentation, are satisfied by the data.

g_A/g_V FOR $\Lambda \to pe^-\overline{\nu}_e$

Measurements with fewer than 500 events have been omitted. Where necessary, signs have been changed to agree with our conventions, which are given in the "Note on Baryon Decay Parameters" in the neutron Listings. The measurements all assume that the form factor $g_2 = 0$. See also the footnote on DWORKIN 90.

[11] The tabulated result assumes the weak-magnetism coupling $w \equiv g_W(0)/g_V(0)$ to be 0.97, as given by the CVC hypothesis and as assumed by the other listed measurements. However, DWORKIN 90 *measures* w to be 0.15 ± 0.30, and then $g_A/g_V = -0.731 \pm 0.016$.

[12] This experiment measures only the absolute value of g_A/g_V.

Λ AND Σ RESONANCES

Introduction: This was a big year for these resonances: two papers—see the $\Lambda(1405)$ and $\Lambda(1670)$. The field remains at a standstill and will only be revived if a kaon factory is built. What follows is a much abbreviated version of the note on Λ and Σ Resonances from our 1990 edition [1]. In particular, see that edition for some representative Argand plots from partial-wave analyses.

Table 1 is an attempt to evaluate the status, both overall and channel by channel, of each Λ and Σ resonance in the Particle Listings. The evaluations are of course partly subjective. A blank indicates there is no evidence at all: either the relevant couplings are small or the resonance does not really exist. The main Baryon Summary Table includes only the established resonances (overall status 3 or 4 stars). A number of the 1- and 2-star entries may eventually disappear, but there are certainly many resonances yet to be discovered underlying the established ones.

Sign conventions for resonance couplings: In terms of the isospin-0 and -1 elastic scattering amplitudes A_0 and A_1, the amplitude for $K^- p \to \overline{K}^0 n$ scattering is $\pm(A_1 - A_0)/2$, where the sign depends on conventions used in conjunction with the Clebsch-Gordan coefficients (such as, is the baryon or the meson the "first" particle). If this reaction is partial-wave analyzed and if the overall phase is chosen so that, say, the $\Sigma(1775) D_{15}$ amplitude at resonance points along the positive imaginary axis (points "up"), then any Σ at resonance will point "up" and any Λ at resonance will point "down" (along the negative imaginary axis). Thus the phase at resonance determines the isospin. The above ignores background amplitudes in the resonating partial waves.

That is the basic idea. In a similar but somewhat more complicated way, the phases of the $\overline{K}N \to \Lambda\pi$ and $\overline{K}N \to \Sigma\pi$ amplitudes for a resonating wave help determine the SU(3) multiplet to which the resonance belongs. Again, a convention has to be adopted for some overall arbitrary phases: which way is "up"? Our convention is that of Levi-Setti [2] and is shown in Fig. 1, which also compares experimental results with theoretical predictions for the signs of several resonances. In the Listings, a + or − sign in front of a measurement of an inelastic resonance coupling indicates the sign (the *absence* of a sign means that the sign is not determined, *not* that it is positive). For more details, see Appendix II of our 1982 edition [3].

Errors on masses and widths: The errors quoted on resonance parameters from partial-wave analyses are often only statistical, and the parameters can change by more than these errors when a different parametrization of the waves is used. Furthermore, the different analyses use more or less the same data, so it is not really appropriate to treat the different determinations of the resonance parameters as independent or to average them together. In any case, the spread of the masses, widths, and branching fractions from the different analyses is certainly a better indication of the uncertainties than are the quoted errors. In the Baryon Summary Table, we usually give a range reflecting the spread of the values rather than a particular value with error.

For three states, the $\Lambda(1520)$, the $\Lambda(1820)$, and the $\Sigma(1775)$, there is enough information to make an overall fit to the various branching fractions. It is then necessary to use the quoted errors, but the errors obtained from the fit should not be taken seriously.

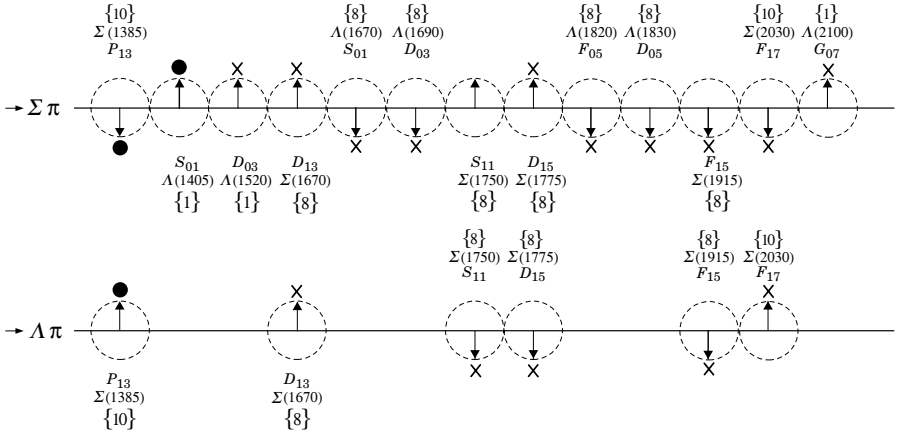

Figure 1. The signs of the imaginary parts of resonating amplitudes in the $\overline{K}N \to \Lambda\pi$ and $\Sigma\pi$ channels. The signs of the $\Sigma(1385)$ and $\Lambda(1405)$, marked with a •, are set by convention, and then the others are determined relative to them. The signs required by the SU(3) assignments of the resonances are shown with an arrow, and the experimentally determined signs are shown with an ×.

Table 1. The status of the Λ and Σ resonances. Only those with an overall status of *** or **** are included in the main Baryon Summary Table.

Particle	$L_{I\,2J}$	Overall status	Status as seen in — $N\overline{K}$	$\Lambda\pi$	$\Sigma\pi$	Other channels

**** Existence is certain, and properties are at least fairly well explored.
*** Existence ranges from very likely to certain, but further confirmation is desirable and/or quantum numbers, branching fractions, *etc.* are not well determined.
** Evidence of existence is only fair.
* Evidence of existence is poor.

Production experiments: Partial-wave analyses of course separate partial waves, whereas a peak in a cross section or an invariant mass distribution usually cannot be disentangled from background and analyzed for its quantum numbers; and more than one resonance may be contributing to the peak. Results from partial-wave analyses and from production experiments are generally kept separate in the Listings, and in the Baryon Summary Table results from production experiments are used only for the low-mass states. The $\Sigma(1385)$ and $\Lambda(1405)$ of course lie below the $\overline{K}N$ threshold and nearly everything about them is learned from production experiments; and production and formation experiments agree quite well in the case of $\Lambda(1520)$ and results have been combined. There is some disagreement between production and formation experiments in the 1600–1700 MeV region: see the note on the $\Sigma(1670)$.

Λ(1405) FOOTNOTES

[1] DALITZ 91 fits the HEMINGWAY 85 data.
[2] THOMAS 73 data is fit by CHAO 73 (see next section).
[3] The KIMURA 00 values are from fits A and B from a coupled-channel potential model using low-energy $\overline{K}N$ and $\Sigma\pi$ data, kaonic-hydrogen x-ray measurements, and our Λ(1405) mass and width. The results bear mainly on the *nature* of the Λ(1405): three-quark state or $\overline{K}N$ bound state.
[4] The MARTIN 81 fit includes the $K^\pm p$ forward scattering amplitudes and the dispersion relations they must satisfy.
[5] See also the accompanying paper of THOMAS 73.
[6] Data of SAKITT 65 are used in the fit by KITTEL 66.
[7] An asymmetric shape, with $\Gamma/2 = 41$ MeV below resonance, 14 MeV above.

Λ(1520) D_{03}

$I(J^P) = 0(\frac{3}{2}^-)$ Status: ****

Discovered by FERRO-LUZZI 62; the elaboration in WATSON 63 is the classic paper on the Breit-Wigner analysis of a multichannel resonance.

The measurements of the mass, width, and elasticity published before 1975 are now obsolete and have been omitted. They were last listed in our 1982 edition Physics Letters **111B** (1982).

Production and formation experiments agree quite well, so they are listed together here.

CONSTRAINED FIT INFORMATION

An overall fit to 9 branching ratios uses 24 measurements and one constraint to determine 6 parameters. The overall fit has a $\chi^2 = 16.5$ for 19 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

x_2	−63				
x_3	−32	−33			
x_7	−4	−3	−1		
x_8	−9	−8	−4	0	
x_9	−24	−21	−10	−1	−2
	x_1	x_2	x_3	x_7	x_8

Γ(Σ(1385)π(→ Λππ))/Γ(Λππ) — Γ5/Γ3

The Λππ mode is largely due to Σ(1385)π. Only the values of (Σ(1385)π) / (Λ2π) given by MAST 73B and CORDEN 75 are based on real 3-body partial-wave analyses. The discrepancy between the two results is essentially due to the different hypotheses made concerning the shape of the $(\pi\pi)_{S\text{-wave}}$ state.

Λ(1520) FOOTNOTES

[1] From the best-resolution sample of Λππ events only.
[2] The $\overline{K}N \to \Sigma\pi$ amplitude at resonance is +0.46 ± 0.01.
[3] Assumes $\Gamma(N\overline{K})/\Gamma_{\text{total}} = 0.46 \pm 0.02$.
[4] Both Σ(1385)π DS_{03} and Σ(ππ) DP_{03} contribute.
[5] The central bin (1514–1524 MeV) gives 0.74 ± 0.10; other bins are lower by 2-to-5 standard deviations.
[6] Much of the Σππ decay proceeds via Σ(1385)π.
[7] Assumes $\Gamma(N\overline{K})/\Gamma_{\text{total}} = 0.46$.
[8] Calculated from $\Gamma(\Lambda\gamma)/\Gamma_{\text{total}}$, assuming SU(3). Needed to constrain the sum of all the branching ratios to be unity.

$\Lambda(1670)$ FOOTNOTES

[1] GARCIA-RECIO 03 gives pole, not Breit-Wigner, parameters, but the narrow width of the $\Lambda(1670)$ means there will be little difference.
[2] MARTIN 77 obtains identical resonance parameters from a T-matrix pole and from a Breit-Wigner fit.

$\Lambda(1690)$ DECAY MODES

	Mode	Fraction (Γ_i/Γ)
Γ_1	$N\overline{K}$	20–30 %
Γ_2	$\Sigma\pi$	20–40 %
Γ_3	$\Lambda\pi\pi$	~ 25 %
Γ_4	$\Sigma\pi\pi$	~ 20 %
Γ_5	$\Lambda\eta$	
Γ_6	$\Sigma(1385)\pi$, *S*-wave	

The above branching fractions are our estimates, not fits or averages.

$\Lambda(1690)$ BRANCHING RATIOS

The sum of all the quoted branching ratios is more than 1.0. The two-body ratios are from partial-wave analyses, and thus probably are more reliable than the three-body ratios, which are determined from bumps in cross sections. Of the latter, the $\Sigma\pi\pi$ bump looks more significant. (The error given for the $\Lambda\pi\pi$ ratio looks unreasonably small.) Hardly any of the $\Sigma\pi\pi$ decay can be via $\Sigma(1385)$, for then seven times as much $\Lambda\pi\pi$ decay would be required. See "Sign conventions for resonance couplings" in the Note on Λ and Σ Resonances.

$\Lambda(1690)$ FOOTNOTES

[1] The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit. Another D_{03} Λ at 1966 MeV is also suggested by MARTIN 77, but is very uncertain.
[2] BARTLEY 68 uses only cross-section data. The enhancement is not seen by PREVOST 71.

Λ(1820) F_{05}

$I(J^P) = 0(\frac{5}{2}^+)$ Status: ****

This resonance is the cornerstone for all partial-wave analyses in this region. Most of the results published before 1973 are now obsolete and have been omitted. They may be found in our 1982 edition Physics Letters **111B** (1982).

Most of the quoted errors are statistical only; the systematic errors due to the particular parametrizations used in the partial-wave analyses are not included. For this reason we do not calculate weighted averages for the mass and width.

Λ(1820) FOOTNOTES

[1] The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit.
[2] There is a suggestion of a bump, enough to be consistent with what is expected from $\Sigma(1385) \to \Sigma\pi$ decay.
[3] The published sign has been changed to be in accord with the baryon-first convention.

Λ(2000) $I(J^P) = 0(?^?)$ Status: *

OMITTED FROM SUMMARY TABLE

We list here all the ambiguous resonance possibilities with a mass around 2 GeV. The proposed quantum numbers are D_3 (BARBARO-GALTIERI 70 in $\Sigma\pi$), D_3+F_5, P_3+D_5, or P_1+D_3 (BRANDSTETTER 72 in $\Lambda\omega$), and S_1 (CAMERON 78B in $N\overline{K}^*$). The first two of the above analyses should now be considered obsolete. See also NAKKASYAN 75.

Λ(2000) FOOTNOTES

[1] The parameters quoted here are ranges from the three best fits; the lower state probably has $J \leq 3/2$, and the higher one probably has $J \leq 5/2$.
[2] The published sign has been changed to be in accord with the baryon-first convention.

Λ(2020) F_{07} $I(J^P) = 0(\frac{7}{2}^+)$ Status: *

OMITTED FROM SUMMARY TABLE

In LITCHFIELD 71, need for the state rests solely on a possibly inconsistent polarization measurement at 1.784 GeV/c. HEMINGWAY 75 does not require this state. GOPAL 77 does not need it in either $N\overline{K}$ or $\Sigma\pi$. With new $K^- n$ angular distributions included, DECLAIS 77 sees it. However, this and other new data are included in GOPAL 80 and the state is not required. BACCARI 77 weakly supports it.

Λ(2100) G_{07}

$I(J^P) = 0(\frac{7}{2}^-)$ Status: ****

Discovered by COOL 66 and by WOHL 66. Most of the results published before 1973 are now obsolete and have been omitted. They may be found in our 1982 edition Physics Letters **111B** (1982).

This entry only includes results from partial-wave analyses. Parameters of peaks seen in cross sections and in invariant-mass distributions around 2100 MeV used to be listed in a separate entry immediately following. It may be found in our 1986 edition Physics Letters **170B** (1986).

Λ(2100) FOOTNOTES

[1] The NAKKASYAN 75 values are from the two best solutions found. Each has the Λ(2100) and one additional resonance (P_3 or F_5).

[2] Note that the three for BACCARI 77 entries are for three different waves.

[3] The published sign has been changed to be in accord with the baryon-first convention. The upper limit on the G_3 wave is 0.03.

$I(J^P) = 0(\frac{3}{2}^-)$ Status: *

OMITTED FROM SUMMARY TABLE

BACCARI 77 finds this state with either $J^P = 3/2^-$ or $3/2^+$ in a energy-dependent partial-wave analyses of $K^-p\to\Lambda\omega$ from 2070 to 2436 MeV. A subsequent semi-energy-independent analysis from threshold to 2436 MeV selects $3/2^-$. DEBELLEFON 78 (same group) also sees this state in an energy-dependent partial-wave analysis of $K^-p\to\overline{K}N$ data, and finds $J^P = 3/2^-$ or $3/2^+$. They again prefer $J^P = 3/2^-$, but only on the basis of model-dependent considerations.

0.83 ± 0.032	1300	[4] CHANG	66	HBC	

[3] This is a measurement of the $\overline{\Sigma}^-$ lifetime. Here we assume *CPT* invariance; see below for the fractional Σ^+-$\overline{\Sigma}^-$ lifetime difference obtained by BARBOSA 00.

[4] We have increased the CHANG 66 error of 0.018; see our 1970 edition, Reviews of Modern Physics **42** No. 1 (1970).

$(\tau_{\Sigma^+} - \tau_{\overline{\Sigma}^-}) / \tau_{\Sigma^+}$

A test of *CPT* invariance.

VALUE	DOCUMENT ID		TECN	COMMENT
(−6 ± 12) × 10^{-4}	BARBOSA	00	E761	hyperons, 375 GeV

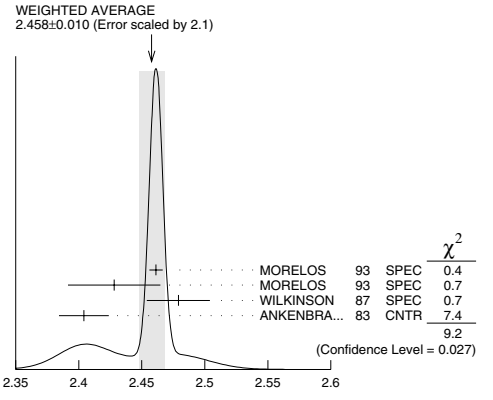
Σ^+ MAGNETIC MOMENT

See the "Note on Baryon Magnetic Moments" in the Λ Listings. Measurements with an error $\geq$ 0.1 μ_N have been omitted.

VALUE (μ_N)	EVTS	DOCUMENT ID		TECN	COMMENT
2.458 ± 0.010 OUR AVERAGE	Error includes scale factor of 2.1. See the ideogram below.				
2.4613 ± 0.0034 ± 0.0040	250k	MORELOS	93	SPEC	pCu 800 GeV
2.428 ± 0.036 ± 0.007	12k	[5] MORELOS	93	SPEC	pCu 800 GeV
2.479 ± 0.012 ± 0.022	137k	WILKINSON	87	SPEC	pBe 400 GeV
2.4040 ± 0.0198	44k	[6] ANKENBRA...	83	CNTR	pCu 400 GeV

[5] We assume *CPT* invariance: this is (minus) the $\overline{\Sigma}^-$ magnetic moment as measured by MORELOS 93. See below for the moment difference testing *CPT*.

[6] ANKENBRANDT 83 gives the value 2.38 ± 0.02μ_N. MORELOS 93 uses the same hyperon magnet and channel and claims to determine the field integral better, leading to the revised value given here.



$(\mu_{\Sigma^+} + \mu_{\overline{\Sigma}^-}) / \mu_{\Sigma^+}$

A test of *CPT* invariance.

VALUE	DOCUMENT ID		TECN	COMMENT
0.014 ± 0.015	[7] MORELOS	93	SPEC	pCu 800 GeV

[7] This is our calculation from the MORELOS 93 measurements of the Σ^+ and $\overline{\Sigma}^-$ magnetic moments given above. The statistical error on $\mu_{\overline{\Sigma}^-}$ dominates the error here.

Σ^+ DECAY MODES

	Mode		Fraction (Γ_i/Γ)		Confidence level

[a] See the Listings below for the pion momentum range used in this measurement.

CONSTRAINED FIT INFORMATION

An overall fit to 2 branching ratios uses 14 measurements and one constraint to determine 3 parameters. The overall fit has a χ^2 = 7.7 for 12 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

x_2	−100		
x_3	12	−14

Σ^0

$I(J^P) = 1(\frac{1}{2}^+)$ Status: ****

COURANT 63 and ALFF-STEINBERGER 65, using $\Sigma^0 \to \Lambda e^+ e^-$ decays (Dalitz decays), determined the Σ^0 parity to be positive, given that $J = 1/2$ and that certain very reasonable assumptions about form factors are true. The results of experiments involving the Primakoff effect, from which the Σ^0 mean life and $\Sigma^0 \to \Lambda$ transition magnetic moment come (see below), strongly support $J = 1/2$.

Σ^0 MASS

The fit uses Σ^+, Σ^0, Σ^-, and Λ mass and mass-difference measurements.

Σ^0 MEAN LIFE

These lifetimes are deduced from measurements of the cross sections for the Primakoff process $\Lambda \to \Sigma^0$ in nuclear Coulomb fields. An alternative expression of the same information is the Σ^0-Λ transition magnetic moment given in the following section. The relation is $(\mu_{\Sigma\Lambda}/\mu_N)^2\,\tau = 1.92951 \times 10^{-19}$ s (see DEVLIN 86).

Γ_5	$\Lambda e^-\overline{\nu}_e$	(5.73 ±0.27) × 10^{-5}

[a] See the Listings below for the pion momentum range used in this measurement.

CONSTRAINED FIT INFORMATION

An overall fit to 3 branching ratios uses 16 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2 = 8.7$ for 13 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

g_A/g_V FOR $\Sigma^- \to ne^-\overline{\nu}_e$

Measurements with fewer than 500 events have been omitted. Where necessary, signs have been changed to agree with our conventions, which are given in the "Note on Baryon Decay Parameters" in the neutron Listings. What is actually listed is $|g_1/f_1 - 0.237 g_2/f_1|$. This reduces to $g_A/g_V \equiv g_1(0)/f_1(0)$ on making the usual assumption that $g_2 = 0$. See also the note on HSUEH 88.

VALUE	EVTS	DOCUMENT ID		TECN	COMMENT
0.340±0.017 OUR AVERAGE					
+0.327±0.007±0.019	50k	[7] HSUEH	88	SPEC	Σ^- 250 GeV
+0.34 ±0.05	4456	[8] BOURQUIN	83C	SPEC	SPS hyperon beam

• • • We do not use the following data for averages, fits, limits, etc. • • •					
0.29 ±0.07	25k	HSUEH	85	SPEC	See HSUEH 88
$0.17^{+0.07}_{-0.09}$	519	DECAMP	77	ELEC	Hyperon beam

[7] The sign is, *with our conventions*, unambiguously positive. The value assumes, as usual, that $g_2 = 0$. If g_2 is included in the fit, than (with our sign convention) $g_2 = -0.56 \pm 0.37$, with a corresponding reduction of g_A/g_V to $+0.20 \pm 0.08$.

[8] BOURQUIN 83C favors the positive sign by at least 2.6 standard deviations.

[9] TANENBAUM 74 gives 0.435 ± 0.035, assuming no q^2 dependence in g_A and g_V. The listed result allows q^2 dependence, and is taken from HSUEH 88.

$f_2(0)/f_1(0)$ FOR $\Sigma^- \to ne^-\overline{\nu}_e$

The signs have been changed to be in accord with our conventions, given in the "Note on Baryon Decay Parameters" in the neutron Listings.

TRIPLE CORRELATION COEFFICIENT D for $\Sigma^- \to ne^-\overline{\nu}_e$

The coefficient D of the term $D\,\mathbf{P}\cdot(\mathbf{p}_e\times\mathbf{p}_\nu)$ in the $\Sigma^- \to ne^-\overline{\nu}$ decay angular distribution. A nonzero value would indicate a violation of time-reversal invariance.

VALUE	EVTS	DOCUMENT ID		TECN	COMMENT
0.11±0.10	50k	HSUEH	88	SPEC	Σ^- 250 GeV

g_V/g_A FOR $\Sigma^- \to \Lambda e^-\overline{\nu}_e$

For the sign convention, see the "Note on Baryon Decay Parameters" in the neutron Listings. The value is predicted to be zero by conserved vector current theory. The values averaged assume CVC-SU(3) weak magnetism term.

VALUE	EVTS	DOCUMENT ID		TECN	COMMENT
0.01 ±0.10 OUR AVERAGE		Error includes scale factor of 1.5. See the ideogram below.

$\Sigma(1385)\ P_{13}$

$I(J^P) = 1(\frac{3}{2}^+)$ Status: ****

Discovered by ALSTON 60. Early measurements of the mass and width for combined charge states have been omitted. They may be found in our 1984 edition Reviews of Modern Physics **56** No. 2 Pt. II (1984).

We average only the most significant determinations. We do not average results from inclusive experiments with large backgrounds or results which are not accompanied by some discussion of experimental resolution. Nevertheless systematic differences between experiments remain. (See the ideograms in the Listings below.) These differences could arise from interference effects that change with production mechanism and/or beam momentum. They can also be accounted for in part by differences in the parametrizations employed. (See BORENSTEIN 74 for a discussion on this point.) Thus BORENSTEIN 74 uses a Breit-Wigner with energy-independent width, since a P-wave was found to give unsatisfactory fits. CAMERON 78 uses the same form. On the other hand HOLMGREN 77 obtains a good fit to their $\Lambda\pi$ spectrum with a P-wave Breit-Wigner, but includes the partial width for the $\Sigma\pi$ decay mode in the parametrization. AGUILAR-BENITEZ 81D gives masses and widths for five different Breit-Wigner shapes. The results vary considerably. Only the best-fit S-wave results are given here.

$I(J^P) = 1(?^?)$ Status: *

OMITTED FROM SUMMARY TABLE

These are peaks seen in $\Lambda\pi$ and $\Sigma\pi$ spectra in the reaction $\pi^+p \to (Y\pi)K^+$ at 1.7 GeV/c. Also, the Y polarization oscillates in the same region.

MILLER 70 suggests a possible alternate explanation in terms of a reflection of $N(1675) \to \Lambda K$ decay. However, such an explanation for the $(\Sigma^+\pi^0)K^+$ channel in terms of $\Delta(1650) \to \Sigma K$ decay seems unlikely (see PAN 70). In addition such reflections would also have to account for the oscillation of the Y polarization in the 1480 MeV region.

HANSON 71, with less data than PAN 70, can neither confirm nor deny the existence of this state. MAST 75 sees no structure in this region in $K^-p \to \Lambda\pi^0$.

ENGELEN 80 performs a multichannel analysis of $K^-p \to p\overline{K}^0\pi^-$ at 4.2 GeV/c. They observe a 3.5 standard-deviation signal at 1480 MeV in $p\overline{K}^0$ which cannot be explained as a reflection of any competing channel.

$\Sigma(1560)$ Bumps

$I(J^P) = 1(?^?)$ Status: **

OMITTED FROM SUMMARY TABLE

This entry lists peaks reported in mass spectra around 1560 MeV without implying that they are necessarily related.

DIONISI 78B observes a 6 standard-deviation enhancement at 1553 MeV in the charged $\Lambda/\Sigma\pi$ mass spectra from $K^-p\to(\Lambda/\Sigma)\pi K\overline{K}$ at 4.2 GeV/c. In a CERN ISR experiment, LOCKMAN 78 reports a narrow 6 standard-deviation enhancement at 1572 MeV in $\Lambda\pi^\pm$ from the reaction $pp\to\Lambda\pi^+\pi^-X$. These enhancements are unlikely to be associated with the $\Sigma(1580)$ (which has not been confirmed by several recent experiments – see the next entry in the Listings).

CARROLL 76 observes a bump at 1550 MeV (as well as one at 1580 MeV) in the isospin-1 $\overline{K}N$ total cross section, but uncertainties in cross section measurements outside the mass range of the experiment preclude estimating its significance.

See also MEADOWS 80 for a review of this state.

$\Sigma(1580)$ FOOTNOTES

[1] CARROLL 76 sees a total-cross-section bump with $(J+1/2)\ \Gamma_{el}/\Gamma_{total}=0.06$.

[2] The main effect observed by LITCHFIELD 74 is in the $\Lambda\pi$ final state; the $\overline{K}N$ and $\Sigma\pi$ couplings are estimated from a multichannel fit including total-cross-section data of LI 73.

OMITTED FROM SUMMARY TABLE

Formation experiments are listed separately in the previous entry.

The results of CRENNELL 69B at 3.9 GeV/c are not confirmed by SABRE 70 at 3.0 GeV/c. However, at 4.5 GeV/c, AMMANN 70 sees a peak at 1642 MeV which on the basis of branching ratios they do not associate with the $\Sigma(1670)$. See MILLER 70 for a review of these conflicts.

THE $\Sigma(1670)$ REGION

Production experiments: The measured $\Sigma\pi/\Sigma\pi\pi$ branching ratio for the $\Sigma(1670)$ produced in the reaction $K^- p \to \pi^- \Sigma(1670)^+$ is strongly dependent on momentum transfer. This was first discovered by EBERHARD 69, who suggested that there exist two Σ resonances with the same mass and quantum numbers: one with a large $\Sigma\pi\pi$ (mainly $\Lambda(1405)\pi$) branching fraction produced peripherally, and the other with a large $\Sigma\pi$ branching fraction produced at larger angles. The experimental results have been confirmed by AGUILAR-BENITEZ 70, ASPELL 74, ESTES 74, and TIMMERMANS 76. If, in fact, there are two resonances, the most likely quantum numbers for both the $\Sigma\pi$ and the $\Lambda(1405)\pi$ states are D_{13}. There is also possibly a third Σ in this region, the $\Sigma(1690)$ in the Listings, the main evidence for which is a large $\Lambda\pi/\Sigma\pi$ branching ratio. These topics have been reviewed by EBERHARD 73 and by MILLER 70.

Formation experiments: Two states are also observed near this mass in formation experiments. One of these, the $\Sigma(1670)D_{13}$, has the same quantum numbers as those observed in production and has a large $\Sigma\pi/\Sigma\pi\pi$ branching ratio; it may well be the $\Sigma(1670)$ produced at larger angles (see TIMMERMANS 76). The other state, the $\Sigma(1660)P_{11}$, has different quantum numbers, its $\Sigma\pi/\Sigma\pi\pi$ branching ratio is unknown, and its relation to the produced $\Sigma(1670)$ states is obscure.

$\Sigma(1670)$ D_{13}

$I(J^P) = 1(\frac{3}{2}^-)$ Status: ****

For most results published before 1974 (they are now obsolete), see our 1982 edition Physics Letters **111B** (1982).

Results from production experiments are listed separately in the next entry.

0.081 ± 0.016	[6] CAMERON	77	DPWA	P-wave decay

$\Sigma(1670)$ FOOTNOTES

[1] The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit.
[2] Results are with and without an S_{11} $\Sigma(1620)$ in the fit.
[3] SIMS 68 uses only cross-section data. Result used as upper limit only.
[4] Ratio only for $\Sigma 2\pi$ system in $I = 1$, which cannot be $\Sigma(1385)$.
[5] Assuming the $\Lambda(1405)\pi$ cross-section bump is due only to $3/2^-$ resonance.
[6] The CAMERON 77 upper limit on F-wave decay is 0.03.

$\Sigma(1670)$, $\Sigma(1670)$ Bumps

$\Sigma(1670)$ Bumps

$I(J^P) = 1(?^?)$

OMITTED FROM SUMMARY TABLE

Formation experiments are listed separately in the preceding entry.

Probably there are two states at the same mass with the same quantum numbers, one decaying to $\Sigma\pi$ and $\Lambda\pi$, the other to $\Lambda(1405)\pi$. See the note in front of the preceding entry.

$\Sigma(1690)$ FOOTNOTES (PRODUCTION EXPERIMENTS)

[1] From $\pi^+ p \to (\Lambda\pi^+) K^+$. $J > 1/2$ is not required by the data.
[2] From $\pi^+ p \to (\Lambda\pi^+)(K\pi)^+$. $J > 1/2$ is indicated, but large background precludes a definite conclusion.
[3] See the $\Sigma(1670)$ Listings. AGUILAR-BENITEZ 70B with three times the data of PRIMER 68 find no evidence for the $\Sigma(1690)$.
[4] This analysis, which is difficult and requires several assumptions and shows no unambiguous $\Sigma(1690)$ signal, suggests $J^P = 5/2^+$. Such a state would lead all previously known Y^* trajectories.

$\Sigma(1750)$ S_{11}

$I(J^P) = 1(\frac{1}{2}^-)$ Status: ***

For most results published before 1974 (they are now obsolete), see our 1982 edition Physics Letters **111B** (1982).

There is evidence for this state in many partial-wave analyses, but with wide variations in the mass, width, and couplings. The latest analyses indicated significant couplings to $N\overline{K}$ and $\Lambda\pi$, as well as to $\Sigma\eta$ whose threshold is at 1746 MeV (JONES 74).

OMITTED FROM SUMMARY TABLE

Evidence for this state now rests solely on solution 1 of BAILLON 75, (see the footnotes) but the $\Lambda\pi$ partial-wave amplitudes of this solution are in disagreement with amplitudes from most other $\Lambda\pi$ analyses.

$\Sigma(1770)$ FOOTNOTES

[1] Required to fit the isospin-1 total cross section of CARROLL 76 in the $\overline{K}N$ channel. The addition of new $K^- p$ polarization and $K^- n$ differential cross-section data in GOPAL 80 find it to be more consistent with the $\Sigma(1660)$ P_{11}.
[2] From solution 1 of BAILLON 75; not present in solution 2.
[3] Not required in KANE 74, which supersedes KANE 72.

$\Sigma(1775)$ D_{15}

$I(J^P) = 1(\frac{5}{2}^-)$ Status: ****

Discovered by GALTIERI 63, this resonance plays the same role as cornerstone for isospin-1 analyses in this region as the $\Lambda(1820)$ does in the isospin-0 channel.

For most results published before 1974 (they are now obsolete), see our 1982 edition Physics Letters **111B** (1982).

	Mode	Fraction (Γ_i/Γ)
Γ_1	$N\overline{K}$	37–43%
Γ_2	$\Lambda\pi$	14–20%
Γ_3	$\Sigma\pi$	2–5%
Γ_4	$\Sigma(1385)\pi$	8–12%
Γ_5	$\Sigma(1385)\pi$, D-wave	
Γ_6	$\Lambda(1520)\pi$	17–23%
Γ_7	$\Sigma\pi\pi$	

The above branching fractions are our estimates, not fits or averages.

CONSTRAINED FIT INFORMATION

An overall fit to 8 branching ratios uses 16 measurements and one constraint to determine 5 parameters. The overall fit has a $\chi^2 = 63.9$ for 12 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

x_2	−30			
x_3	−17	−21		
x_4	−37	−49	−14	
x_6	−81	6	8	16
	x_1	x_2	x_3	x_4

$\Sigma(1775)$ BRANCHING RATIOS

See "Sign conventions for resonance couplings" in the Note on Λ and Σ Resonances. Also, the errors quoted do not include uncertainties due to the parametrization used in the partial-wave analyses and are thus too small.

$\Sigma(1775)$ FOOTNOTES

[1] The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit.

[2] This rate combines P-wave- and F-wave decays. The CAMERON 77 results for the separate P-wave- and F-wave decays are -0.303 ± 0.010 and -0.037 ± 0.014. The published signs have been changed here to be in accord with the baryon-first convention.

[3] The CAMERON 78 upper limit on G-wave decay is 0.03.

[4] For about 3/4 of this, the $\Sigma\pi$ system has $I = 0$ and is almost entirely $\Lambda(1520)$. For the rest, the $\Sigma\pi$ has $I = 1$, which is about what is expected from the known $\Sigma(1775) \to \Sigma(1385)\pi$ rate, as seen in $\Lambda\pi\pi$.

OMITTED FROM SUMMARY TABLE

A P_{11} resonance is suggested by several partial-wave analyses, but with wide variations in the mass and other parameters. We list here all claims which lie well above the P_{11} $\Sigma(1770)$.

$\Sigma(1880)$ FOOTNOTES

[1] The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit.
[2] From solution 1 of BAILLON 75; not present in solution 2.
[3] Only unconstrained states from table 1 of LEA 73 are listed.
[4] The published sign has been changed to be in accord with the baryon-first convention.

$\Sigma(1915)$ F_{15}

$I(J^P) = 1(\frac{5}{2}^+)$ Status: ****

Discovered by COOL 66. For results published before 1974 (they are now obsolete), see our 1982 edition Physics Letters **111B** (1982).

This entry only includes results from partial-wave analyses. Parameters of peaks seen in cross sections and invariant-mass distributions in this region used to be listed in in a separate entry immediately following. They may be found in our 1986 edition Physics Letters **170B** (1986).

$\Sigma(1915)$ FOOTNOTES

[1] The two entries for CORDEN 77C are from two different acceptable solutions.
[2] Preferred solution 3; see CORDEN 76 for other possibilities.
[3] The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit.
[4] The mass and width are fixed to the GOPAL 77 values due to the low elasticity.
[5] The published sign has been changed to be in accord with the baryon-first convention.

$\Sigma(2250)$

$I(J^P) = 1(?^?)$ Status: ***

Results from partial-wave analyses are too weak to warrant separating them from the production and cross-section experiments. LASINSKI 71 in $\overline{K}N$ using a Pomeron + resonances model, and DEBELLEFON 76, DEBELLEFON 77, and DEBELLEFON 78 in energy-dependent partial-wave analyses of $\overline{K}N \to \Lambda\pi$, $\Sigma\pi$, and $N\overline{K}$, respectively, suggest two resonances around this mass.

$\Sigma(3170)$ Bumps

$I(J^P) = 1(?^?)$ Status: *

OMITTED FROM SUMMARY TABLE

Seen by AMIRZADEH 79 as a narrow 6.5-standard-deviation enhancement in the reaction $K^- p \to Y^{*+}\pi^-$ using data from independent high statistics bubble chamber experiments at 8.25 and 6.5 GeV/c. The dominant decay modes are multibody, multistrange final states and the production is via isospin-3/2 baryon exchange. Isospin 1 is favored.

Not seen in a $K^- p$ experiment in LASS at 11 GeV/c (ASTON 85B).

CONSTRAINED FIT INFORMATION

An overall fit to 3 branching ratios uses 6 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2 = 4.4$ for 3 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\rm total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

[6] The errors have been multiplied by 1.2 due to approximations used for the Ξ polarization; see DAUBER 69 for a discussion.

RADIATIVE HYPERON DECAYS

Written September 2003 by J.D. Jackson (LBNL).

The weak radiative decays of spin-1/2 hyperons, $B_i \rightarrow B_f\gamma$, yield information about matrix elements (form factors) similar to that gained from weak hadronic decays. For a polarized spin-1/2 hyperon decaying radiatively via a $\Delta Q = 0$, $\Delta S = 1$ transition, the angular distribution of the direction $\hat{\mathbf{p}}$ of the final spin-1/2 baryon in the hyperon rest frame is

$$\frac{dN}{d\Omega} = \frac{N}{4\pi}\,(1 + \alpha_\gamma\,\mathbf{P}_i\cdot\hat{\mathbf{p}})\ . \qquad (1)$$

Here $\mathbf{P}_i$ is the polarization of the decaying hyperon, and α_γ is the asymmetry parameter. In terms of the form factors $F_1(q^2)$, $F_2(q^2)$, and $G(q^2)$ of the effective hadronic weak electromagnetic vertex,

$$F_1(q^2)\gamma_\lambda + iF_2(q^2)\sigma_{\lambda\mu}q^\mu + G(q^2)\gamma_\lambda\gamma_5\ ,$$

α_γ is

$$\alpha_\gamma = \frac{2\,\mathrm{Re}[G(0)F_M^*(0)]}{|G(0)|^2 + |F_M(0)|^2}\ , \qquad (2)$$

where $F_M = (m_i - m_f)[F_2 - F_1/(m_i + m_f)]$. If the decaying hyperon is unpolarized, the decay baryon has a longitudinal polarization given by $P_f = -\alpha_\gamma$ [1].

The angular distribution for the weak hadronic decay, $B_i \rightarrow B_f\pi$, has the same form as Eq. (1), but of course with a different asymmetry parameter, α_π. Now, however, if the decaying hyperon is unpolarized, the decay baryon has a longitudinal polarization given by $P_f = +\alpha_\pi$ [2,3]. The difference of sign is because the spins of the pion and photon are different.

$\Xi^0 \rightarrow \Lambda\gamma$ decay—The radiative decay $\Xi^0 \rightarrow \Lambda\gamma$ of an unpolarized Ξ^0 uses the hadronic decay $\Lambda \rightarrow p\pi^-$ as the analyzer. As noted above, the longitudinal polarization of the Λ will be $P_\Lambda = -\alpha_{\Xi\Lambda\gamma}$. Let α_- be the $\Lambda \rightarrow p\pi^-$ asymmetry parameter and $\theta_{\Lambda p}$ be the angle, as seen in the Λ rest frame, between the Λ line of flight and the proton momentum. Then the hadronic version of Eq. (1) applied to the $\Lambda \rightarrow p\pi^-$ decay gives

$$\frac{dN}{d\cos\theta_{\Lambda p}} = \frac{N}{2}\,(1 - \alpha_{\Xi\Lambda\gamma}\,\alpha_-\cos\theta_{\Lambda p}) \qquad (3)$$

for the angular distribution of the proton in the Λ frame. The only published measurement of $\alpha_{\Xi\Lambda\gamma}$ [4] got the sign wrong, as explained in an erratum 12 years later [5]. The corrected result is $\alpha_{\Xi\Lambda\gamma} = -0.43 \pm 0.44$.

$\Xi^0 \rightarrow \Sigma^0\gamma$ decay—The asymmetry parameter here, $\alpha_{\Xi\Sigma\gamma}$, is measured by following the decay chain $\Xi^0 \rightarrow \Sigma^0\gamma$, $\Sigma^0 \rightarrow \Lambda\gamma$, $\Lambda \rightarrow p\pi^-$. Again, for an unpolarized Ξ^0, the longitudinal polarization of the Σ^0 will be $P_\Sigma = -\alpha_{\Xi\Sigma\gamma}$. In the $\Sigma^0 \rightarrow \Lambda\gamma$ decay, a parity-conserving magnetic-dipole transition, the polarization of the Σ^0 is transferred to the Λ, as may be seen as follows. Let $\theta_{\Sigma\Lambda}$ be the angle seen in the Σ^0 rest frame between the Σ^0 line of flight and the Λ momentum. For Σ^0 helicity $+1/2$, the probability amplitudes for positive and negative spin states of the Σ^0 *along the Λ momentum* are $\cos(\theta_{\Sigma\Lambda}/2)$ and $\sin(\theta_{\Sigma\Lambda}/2)$. Then the amplitude for a negative helicity photon and a negative helicity Λ is $\cos(\theta_{\Sigma\Lambda}/2)$, while the amplitude for positive helicities for the photon and Λ is $\sin(\theta_{\Sigma\Lambda}/2)$. For Σ^0 helicity $-1/2$, the amplitudes are interchanged. If the Σ^0 has

longitudinal polarization P_Σ, the probabilities for Λ helicities $\pm 1/2$ are therefore

$$p(\pm 1/2) = \frac{1}{2}(1 \mp P_\Sigma)\cos^2(\theta_{\Sigma\Lambda}/2) + \frac{1}{2}(1 \pm P_\Sigma)\sin^2(\theta_{\Sigma\Lambda}/2) \ , \quad (4)$$

and the longitudinal polarization of the Λ is

$$P_\Lambda = -P_\Sigma \cos\theta_{\Sigma\Lambda} = +\alpha_{\Xi\Sigma\gamma}\cos\theta_{\Sigma\Lambda} \ . \quad (5)$$

Using Eq. (1) for the $\Lambda \to p\pi^-$ decay again, we get for the joint angular distribution of the $\Sigma^0 \to \Lambda\gamma$, $\Lambda \to p\pi^-$ chain,

$$\frac{d^2N}{d\cos\theta_{\Sigma\Lambda}\, d\cos\theta_{\Lambda p}} = \frac{N}{4}\left(1 + \alpha_{\Xi\Sigma\gamma}\cos\theta_{\Sigma\Lambda}\,\alpha_-\cos\theta_{\Lambda p}\right) \ . \quad (6)$$

The KTeV collaboration recently measured $\alpha_{\Xi\Sigma\gamma}$ to be -0.63 ± 0.09 [6]. The only other measurement has been withdrawn [7].

References

1. R.E. Behrends, Phys. Rev. **111**, 1691 (1958); see Eq. (7) or (8).
2. In ancient times, the signs of the asymmetry term in the angular distributions of radiative and hadronic decays of polarized hyperons were sometimes opposite. For roughly 40 years, however, the overwhelming convention has been to make them the same. The aim, not always achieved, is to remove ambiguities.

CONSTRAINED FIT INFORMATION

An overall fit to 4 branching ratios uses 5 measurements and one constraint to determine 5 parameters. The overall fit has a $\chi^2 = 1.0$ for 1 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle\delta x_i\delta x_j\rangle/(\delta x_i\cdot\delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\rm total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

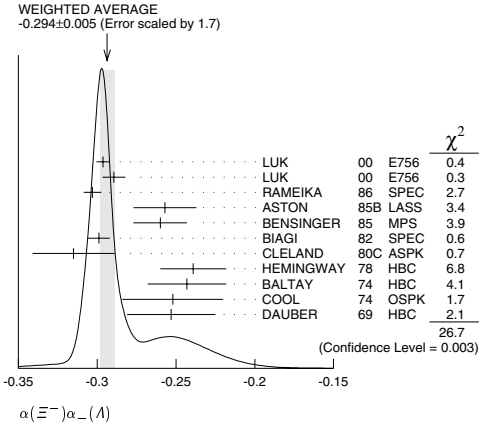
−0.253 ±0.028	2781	DAUBER	69	HBC	

[8] This LUK 00 value is for $\alpha(\overline{\Xi}^+)\,\alpha_+(\overline{\Lambda})$. We assume CP conservation here by including it in the average for $\alpha(\Xi^-)\,\alpha_-(\Lambda)$. But see the second data block below for the CP test.



α FOR $\Xi^- \to \Lambda\pi^-$

The above average, $\alpha(\Xi^-)\,\alpha_-(\Lambda) = -0.293 \pm 0.007$, where the error includes a scale factor of 1.8, divided by our current average $\alpha_-(\Lambda) = 0.642 \pm 0.013$, gives the following value for $\alpha(\Xi^-)$.

VALUE	DOCUMENT ID
−0.458±0.012 OUR EVALUATION	Error includes scale factor of 1.8.

$\frac{[\alpha(\Xi^-)\alpha_-(\Lambda)-\alpha(\overline{\Xi}^+)\alpha_+(\overline{\Lambda})]}{[\alpha(\Xi^-)\alpha_-(\Lambda)+\alpha(\overline{\Xi}^+)\alpha_+(\overline{\Lambda})]}$

This is zero if CP is conserved. The α's are the decay-asymmetry parameters for $\Xi^- \to \Lambda\pi^-$ and $\Lambda \to p\pi^-$ and for $\overline{\Xi}^+ \to \overline{\Lambda}\pi^+$ and $\overline{\Lambda} \to \overline{p}\pi^-$.

VALUE	EVTS	DOCUMENT ID		TECN	COMMENT

Ξ RESONANCES

The accompanying table gives our evaluation of the present status of the Ξ resonances. Not much is known about Ξ resonances. This is because (1) they can only be produced as a part of a final state, and so the analysis is more complicated than if direct formation were possible, (2) the production cross sections are small (typically a few μb), and (3) the final states are topologically complicated and difficult to study with electronic techniques. Thus early information about Ξ resonances came entirely from bubble chamber experiments, where the numbers of events are small, and only in the 1980's did electronic experiments make any significant contributions. However, nothing of significance on Ξ resonances has been added since our 1988 edition.

For a detailed earlier review, see Meadows [1].

Table 1. The status of the Ξ resonances. Only those with an overall status of *** or **** are included in the Baryon Summary Table.

Particle	$L_{2I\,2J}$	Overall status	Status as seen in — Ξπ	AK	ΣK	Ξ(1530)π	Other channels
Ξ(1318)	P_{11}	****					Decays weakly
Ξ(1530)	P_{13}	****	****				
Ξ(1620)		*	*				
Ξ(1690)		***		***	**		
Ξ(1820)	D_{13}	***	**	***	**	**	
Ξ(1950)		***	**	**		*	
Ξ(2030)	1	***		**	***		
Ξ(2120)		*		*			
Ξ(2250)		**					3-body decays
Ξ(2370)	1	**					3-body decays
Ξ(2500)		*		*	*		3-body decays

**** Existence is certain, and properties are at least fairly well explored.
*** Existence ranges from very likely to certain, but further confirmation is desirable and/or quantum numbers, branching fractions, *etc.* are not well determined.
** Evidence of existence is only fair.
* Evidence of existence is poor.

Reference

1. B.T. Meadows, in *Proceedings of the IVth International Conference on Baryon Resonances* (Toronto, 1980), ed. N. Isgur, p. 283.

Ξ(1530) P_{13}

$I(J^P) = \frac{1}{2}(\frac{3}{2}^+)$ Status: ****

This is the only Ξ resonance whose properties are all reasonably well known. Spin-parity $3/2^+$ is favored by the data.

We use only those determinations of the mass and width that are accompanied by some discussion of systematics and resolution.

Ξ(1690)

$I(J^P) = \frac{1}{2}(?^?)$ Status: ***

DIONISI 78 sees a threshold enhancement in both the neutral and negatively charged $\Sigma\overline{K}$ mass spectra in $K^-p \to (\Sigma\overline{K})K\pi$ at 4.2 GeV/c. The data from the $\Sigma\overline{K}$ channels alone cannot distinguish between a resonance and a large scattering length. Weaker evidence at the same mass is seen in the corresponding $\Lambda\overline{K}$ channels, and a coupled-channel analysis yields results consistent with a new Ξ.

BIAGI 81 sees an enhancement at 1700 MeV in the diffractively produced ΛK^- system. A peak is also observed in the $\Lambda\overline{K}^0$ mass spectrum at 1660 MeV that is consistent with a 1720 MeV resonance decaying to $\Sigma^0\overline{K}^0$, with the γ from the Σ^0 decay not detected.

BIAGI 87 provides further confirmation of this state in diffractive dissociation of Ξ^- into ΛK^-. The significance claimed is 6.7 standard deviations.

ADAMOVICH 98 sees a peak of 1400 ± 300 events in the $\Xi^-\pi^+$ spectrum produced by 345 GeV/c Σ^--nucleus interactions.

Ξ(1820) D_{13}

$I(J^P) = \frac{1}{2}(\frac{3}{2}^-)$ Status: ***

The clearest evidence is an 8-standard-deviation peak in ΛK^- seen by GAY 76C. TEODORO 78 favors J=3/2, but cannot make a parity discrimination. BIAGI 87C is consistent with J=3/2 and favors negative parity for this J value.

Ξ(1820) MASS

We only average the measurements that appear to us to be most significant and best determined.

Ξ(1820) FOOTNOTES

[1] BIAGI 87 also sees weak signals in the in the $\Xi^-\pi^+\pi^-$ channel at 1782.6 ± 1.4 MeV (Γ = 6.0 ± 1.5 MeV) and 1831.9 ± 2.8 MeV (Γ = 9.6 ± 9.9 MeV).

[2] BADIER 72 adds all channels and divides the peak into lower and higher mass regions. The data can also be fitted with a single Breit-Wigner of mass 1800 MeV and width 150 MeV.

[3] From a fit to inclusive $\Xi\pi$, $\Xi\pi\pi$, and ΛK^- spectra.

[4] From a fit to inclusive $\Xi\pi$ and $\Xi\pi\pi$ spectra only.

[5] Including $\Xi\pi\pi$.

[6] DAUBER 69 uses in part the same data as SMITH 65C.

[7] For the decay mode $\Xi^-\pi^+\pi^0$ only. This limit includes $\Xi(1530)\pi$.

[8] Or less. Upper limit for the 3-body decay.

Ξ(1950)

$I(J^P) = \frac{1}{2}(?^?)$ Status: ***

We list here everything reported between 1875 and 2000 MeV. The accumulated evidence for a Ξ near 1950 MeV seems strong enough to include a Ξ(1950) in the main Baryon Table, but not much can be said about its properties. In fact, there may be more than one Ξ near this mass.

$\Xi(2030)$

$I(J^P) = \frac{1}{2}(\geq\frac{5}{2}^?)$ Status: ***

The evidence for this state has been much improved by HEMINGWAY 77, who see an eight standard deviation enhancement in $\Sigma\overline{K}$ and a weaker coupling to $\Lambda\overline{K}$. ALITTI 68 and HEMINGWAY 77 observe no signals in the $\Xi\pi\pi$ (or $\Xi(1530)\pi$) channel, in contrast to DIBIANCA 75. The decay $(\Lambda/\Sigma)\overline{K}\pi$ reported by BARTSCH 69 is also not confirmed by HEMINGWAY 77.

A moments analysis of the HEMINGWAY 77 data indicates at a level of three standard deviations that $J \geq 5/2$.

$\Xi(2120)$ FOOTNOTES

[1] CHLIAPNIKOV 79 does not uniquely identify the K^+ in the $(\overline{\Lambda}K^+)$ X final state. It also reports bumps with fewer events at 2240, 2540, and 2830 MeV.
[2] GAY 76C sees a 4-standard deviation signal. However, HEMINGWAY 77, with more events from the same experiment points out that the signal is greatly reduced if a cut is made on the 4-momentum u. This suggests an anomalous production mechanism if the $\Xi(2120)$ is real.

Ω BARYONS
($S = -3$, $I = 0$)

$\Omega^- = sss$

Ω^-

$I(J^P) = 0(\frac{3}{2}^+)$ Status: ****

The unambiguous discovery in both production and decay was by BARNES 64. The quantum numbers have not actually been measured, but follow from the assignment of the particle to the baryon decuplet. DEUTSCHMANN 78 and BAUBILLIER 78 rule out $J = 1/2$ and find consistency with $J = 3/2$.

We have omitted some results that have been superseded by later experiments. See our earlier editions.

Ω^- MASS

The fit assumes the Ω^- and $\overline{\Omega}^+$ masses are the same, and averages them together.

1670.6 ± 1.0	1	[2] FRY	55B	EMUL	
1615	1	[4] EISENBERG	54	EMUL	

[1] DIBIANCA 75 gives a mass for each event. We quote the average.

[2] The FRY 55 and FRY 55B events were identified as Ω^- by ALVAREZ 73. The masses assume decay to ΛK^- at rest. For FRY 55B, decay from an atomic orbit could Doppler shift the K^- energy and the resulting Ω^- mass by several MeV. This shift is negligible for FRY 55 because the Ω decay is approximately perpendicular to its orbital velocity, as is known because the Λ strikes the nucleus (L.Alvarez, private communication 1973). We have calculated the error assuming that the orbital n is 4 or larger.

[3] Excluded from the average; the Ω^- lifetimes measured by the experiments differ significantly from other measurements.

[4] The EISENBERG 54 mass was calculated for decay in flight. ALVAREZ 73 has shown that the Ω interacted with an Ag nucleus to give $K^-\,\Xi$Ag.

$\overline{\Omega}^+$ MASS

The fit assumes the Ω^- and $\overline{\Omega}^+$ masses are the same, and averages them together.

CHARMED BARYONS
($C = +1$)

$\Lambda_c^+ = udc$, $\Sigma_c^{++} = uuc$, $\Sigma_c^+ = udc$, $\Sigma_c^0 = ddc$,
$\Xi_c^+ = usc$, $\Xi_c^0 = dsc$, $\Omega_c^0 = ssc$

CHARMED BARYONS

Revised August 2003 by C.G. Wohl (LBNL).

There are eleven known charmed baryons, each with one c quark.* Figure 1(a) shows the mass spectrum, and for comparison Fig. 1(b) shows the spectrum of the lightest strange baryons. The Λ_c and Σ_c spectra ought to look much like the Λ and Σ spectra, since a Λ_c or a Σ_c is obtained from a Λ or a Σ by changing the s quark to a c quark. However, a Ξ or an Ω has more than one s quark, only *one* of which is changed to a c quark to make a Ξ_c or an Ω_c. Thus the Ξ_c and Ω_c spectra ought to be richer than the Ξ or Ω spectra.**

Before discussing the observed spectra, we review the theory of SU(4) multiplets, which tells us what charmed baryons we should expect to find; this is essential, because the spin-parity values given in Fig. 1(a) have not been measured but have been assigned in accord with expectations of the theory.

SU(4) multiplets—Baryons made from u, d, s, and c quarks belong to SU(4) multiplets. The multiplet numerology, analogous to $3\times3\times3 = 10+8_1+8_2+1$ for the subset of baryons made from just u, d, and s quarks, is $4\times4\times4 = 20+20'_1+20'_2+\bar{4}$. Figure 2(a) shows the 20-plet whose bottom level is an SU(3) decuplet, such as the decuplet that includes the $\Delta(1232)$. Figure 2(b) shows the $20'$-plet whose bottom level is an SU(3) octet, such as the octet that includes the nucleon. Figure 2(c) shows the $\bar{4}$ multiplet, an inverted tetrahedron. One level up in each multiplet are the baryons with one c quark. All the baryons in a given multiplet have the same spin and parity. Each N or Δ or SU(3)-singlet-Λ resonance calls for another $20'$- or 20- or $\bar{4}$-plet, respectively.

The flavor symmetries shown in Fig. 2 are of course very badly broken, but the figure is the simplest way to see what charmed baryons should exist. For example, from Fig. 2(b), we expect to find, in the same $J^P = 1/2^+$ $20'$-plet as the nucleon, a Λ_c, a Σ_c, *two* Ξ_c's, and an Ω_c. Note that this Ω_c is not in the same SU(4) multiplet as the famous $J^P = 3/2^+$ Ω^-.

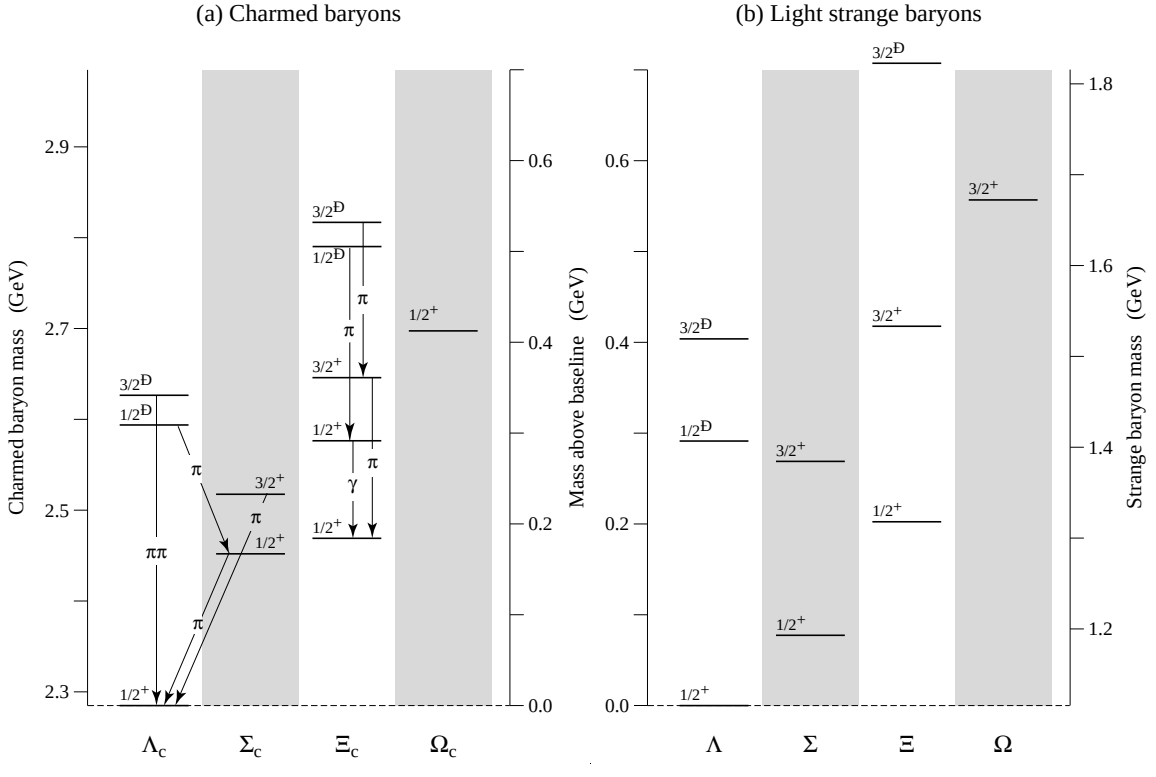

Figure 1. (a) The known charmed baryons, and (b) the lightest strange baryons. The baseline masses are $m(\Lambda_c) = 2284.9$ MeV and $m(\Lambda) = 1115.7$ MeV. Isospin splittings are not shown. Note that there are two $J^P = 1/2^+$ Ξ_c states, and that the Ω_c does not have $J = 3/2$. In fact, none of the J^P values of the charmed baryons has been measured (except perhaps for the $1/2^+\Lambda_c$), but they are all very likely as shown—see the discussion.

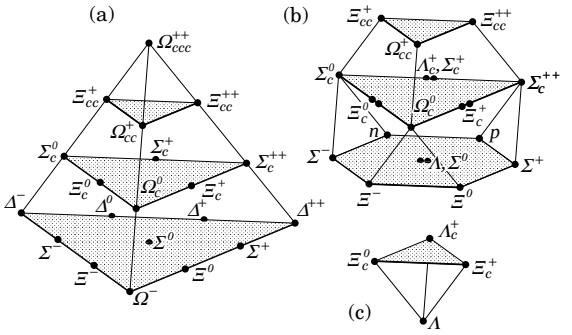

Figure 2: SU(4) multiplets of baryons made of u, d, s, and c quarks. (a) The 20-plet with an SU(3) decuplet on the lowest level. (b) The $20'$-plet with an SU(3) octet on the lowest level. (c) The $\overline{4}$-plet.

Figure 3 shows in more detail the middle level of the $20'$-plet of Fig. 2(b); it splits apart into two SU(3) multiplets, a $\overline{3}$ and a 6. The states of the $\overline{3}$ are antisymmetric under the interchange of the two light quarks (the u, d, and s quarks), whereas the states of the 6 are symmetric under this interchange. We use a prime to distinguish the Ξ_c in the 6 from the one in the $\overline{3}$.

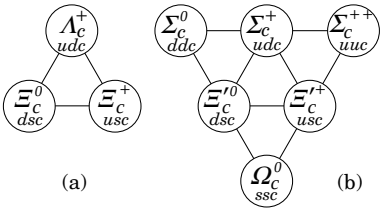

Figure 3: The SU(3) multiplets on the second level of the SU(4) multiplet of Fig. 2(b).

The observed spectra—(1) The parity of the lightest Λ_c is defined to be positive (as are the parities of the p, n, and Λ); the limited evidence about its spin is consistent with $J = 1/2$. However, none of the other J^P quantum numbers given in Fig. 1(a) has been measured. Models using spin-spin and spin-orbit interactions between the quarks, with parameters determined using a few of the masses as input, lead to the J^P assignments shown.† There are no surprises: the $J^P = 1/2^+$ states come first, then the $J^P = 3/2^+$ states ...

(2) There is, however, strong evidence that at least some of the J^P assignments in Fig. 1(a) are correct. As is well known, the successive mass differences between the $J^P = 3/2^+$ particles, the $\Delta(1232)^-$, $\Sigma(1385)^-$, $\Xi(1535)^-$, and Ω^-, which lie along the lower left edge of the 20-plet in Fig. 2(a), should be equal according to SU(3); and indeed experimentally they nearly are. Similarly, the successive mass differences between the $J^P = 1/2^+$ $\Sigma_c(2455)^0$, $\Xi_c'^0$, and Ω_c^0,‡ the particles along the left edge of Fig. 3(b), should be equal—assuming, of course, that they *do* all have the same J^P. And the observed differences are 126.6 ± 3.3 MeV and 118.7 ± 4.1 MeV—not perfect, but close. By the same reasoning, since the mass difference between the presumed $J^P = 3/2^+$ $\Sigma_c(2520)^0$ and $\Xi_c(2645)^0$ is 127.0 ± 2.3 MeV, the $3/2^+$ Ω_c^0 should be at about 2772 MeV.

(3) Other evidence comes from the decay of the $\Lambda_c(2593)$. The only allowed strong decay is $\Lambda_c(2593)^+ \to \Lambda_c^+\pi\pi$, and this appears to be dominated by the submode $\Sigma_c(2455)\pi$, despite little available phase space for the latter (the 'Q' is about 2 MeV, the c.m. decay momentum about 20 MeV/c). Thus the decay is almost certainly s-wave, which, assuming that the $\Sigma_c(2455)$ does indeed have $J^P = 1/2^+$, makes $J^P = 1/2^-$ for the $\Lambda_c(2593)$.

(4) The heavier charmed baryons, such as the $J^P = 1/2^-$ and $3/2^-$ Λ_c's, have much narrower widths than do their strange counterparts, such as the $\Lambda(1405)$ and $\Lambda(1520)$. The clean Λ_c spectrum has in fact been taken to settle the decades-long discussion about the nature of the $\Lambda(1405)$—true 3-quark state or mere $\overline{K}N$ threshold effect?—unambiguously in favor of the first interpretation (which is not to say that the proximity of the $\overline{K}N$ threshold has no effect on the $\Lambda(1405)$). In fact, models of baryon-resonance spectroscopy should now *start* with the narrow charmed baryons, and work back to those broad old resonances.

Footnotes:

* There is evidence for two more baryons with one c quark—a $\Lambda_c(2765)^+$ and a $\Lambda_c(2880)^+$—and for a baryon with *two* c quarks—a Ξ_{cc}^+ at 3519 MeV. However, they have not yet been promoted to the Summary Table. See the Particle Listings.

** For example, there are three Ω_c^0 states (properly symmetrized states of ssc, scs, and css) corresponding to each Ω^- (sss) state.

† This is not the place to discuss the details of the models, nor to attempt a guide to the literature. See the discovery papers of the various charmed baryons for references to the models that lead to the quantum-number assignments.

‡ A reminder about the Particle Data Group naming scheme: A particle that decays strongly has its mass as part of its name; otherwise it doesn't. Thus $\Sigma(1385)$ and $\Sigma_c(2455)$ but Ω^- and Ξ_c'.

Λ_c^+ $I(J^P) = 0(\frac{1}{2}^+)$ Status: ****

The parity of the Λ_c^+ is defined to be positive (as are the parities of the proton, neutron, and Λ). The spin J has not actually been measured yet. Results of an analysis of $pK^-\pi^+$ decays (JEZABEK 92) are consistent with the expected $J = 1/2$. The quark content is udc.

We have omitted some results that have been superseded by later experiments. The omitted results may be found in earlier editions.

Λ_c^+ MASS

Measurements with an error greater than 5 MeV or that are otherwise obsolete have been omitted.

The fit also includes Σ_c–Λ_c^+ and Λ_c^{*+}–Λ_c^+ mass-difference measurements, but this doesn't affect the Λ_c^+ mass.

Λ_c^+ DECAY MODES

Nearly all branching fractions of the Λ_c^+ are measured relative to the $pK^-\pi^+$ mode, but there are no model-independent measurements of this branching fraction. We explain how we arrive at our value of $B(\Lambda_c^+ \to pK^-\pi^+)$ in a Note at the beginning of the branching-ratio measurements, below. When this branching fraction is eventually well determined, all the other branching fractions will slide up or down proportionally as the true value differs from the value we use here.

[a] See the note on "Λ_c^+ Branching Fractions" below.

[b] This branching fraction includes all the decay modes of the final-state resonance.

[c] An ℓ indicates an e or a μ mode, not a sum over these modes.

[d] The value is for the sum of the charge states or particle/antiparticle states indicated.

CONSTRAINED FIT INFORMATION

An overall fit to 6 branching ratios uses 9 measurements and one constraint to determine 5 parameters. The overall fit has a χ^2 = 2.1 for 5 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\rm total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

Λ_c^+ BRANCHING FRACTIONS

Revised 2002 by P.R. Burchat (Stanford University).

Most Λ_c^+ branching fractions are measured relative to the decay mode $\Lambda_c^+ \to pK^-\pi^+$. However, there are no completely model-independent measurements of the absolute branching fraction for $\Lambda_c^+ \to pK^-\pi^+$. Here we describe the measurements that have been used to extract $\mathrm{B}(\Lambda_c^+ \to pK^-\pi^+)$, the model-dependence of the results, and the method we have used to average the results.

ARGUS (ALBRECHT 88C) and CLEO (CRAWFORD 92) measure $\mathrm{B}(\overline{B} \to \Lambda_c^+ \mathrm{X}) \cdot \mathrm{B}(\Lambda_c^+ \to pK^-\pi^+)$ to be $(0.30 \pm 0.12 \pm 0.06)\%$ and $(0.273 \pm 0.051 \pm 0.039)\%$. Under the assumptions that decays of $\overline{B}$ mesons to baryons are dominated by $\overline{B} \to \Lambda_c^+ \mathrm{X}$ and that $\Lambda_c^+ \mathrm{X}$ final states other than $\Lambda_c^+ \overline{N} \mathrm{X}$ can be neglected, they also measure $\mathrm{B}(\overline{B} \to \Lambda_c^+ \mathrm{X})$ to be $(6.8 \pm 0.5 \pm 0.3)\%$ (ALBRECHT 92O) and $(6.4 \pm 0.8 \pm 0.8)\%$ (CRAWFORD 92). Combining these results, we get $\mathrm{B}(\Lambda_c^+ \to pK^-\pi^+) = (4.14 \pm 0.91)\%$. However, the assumption that $\overline{B}$ decay modes to baryons other than $\Lambda_c^+ \overline{N} \mathrm{X}$ are negligible is not on solid ground experimentally or theoretically [2]. Therefore, the branching fraction for $\Lambda_c^+ \to pK^-\pi^+$ given above may be low by some undetermined amount.

A second type of model-dependent determination of $\mathrm{B}(\Lambda_c^+ \to pK^-\pi^+)$ is based on measurements by ARGUS (ALBRECHT 91G) and CLEO (BERGFELD 94) of $\sigma(e^+e^- \to \Lambda_c^+ \mathrm{X}) \cdot \mathrm{B}(\Lambda_c^+ \to \Lambda \ell^+ \nu_\ell) = (4.15 \pm 1.03 \pm 1.18)$ pb and $(4.77 \pm 0.25 \pm 0.66)$ pb. ARGUS (ALBRECHT 96E) and CLEO (AVERY 91) have also measured $\sigma(e^+e^- \to \Lambda_c^+ \mathrm{X}) \cdot \mathrm{B}(\Lambda_c^+ \to pK^-\pi^+)$. The weighted average is (11.2 ± 1.3) pb.

From these measurements, we extract $R \equiv \mathrm{B}(\Lambda_c^+ \to pK^-\pi^+)/\mathrm{B}(\Lambda_c^+ \to \Lambda \ell^+ \nu_\ell) = 2.40 \pm 0.43$. We estimate the $\Lambda_c^+ \to pK^-\pi^+$ branching fraction from the equation

$$\mathrm{B}(\Lambda_c^+ \to pK^-\pi^+) = R\, f\, F\, \frac{\Gamma(D \to \mathrm{X}\ell^+\nu_\ell)}{1 + |V_{cd}/V_{cs}|^2} \cdot \tau(\Lambda_c^+) \ , \quad (1)$$

where $f = \mathrm{B}(\Lambda_c^+ \to \Lambda \ell^+ \nu_\ell)/\mathrm{B}(\Lambda_c^+ \to X_s \ell^+ \nu_\ell)$ and $F = \Gamma(\Lambda_c^+ \to X_s \ell^+ \nu_\ell)/\Gamma(D^0 \to X_s \ell^+ \nu_\ell)$. When we use $1 + |V_{cd}/V_{cs}|^2 = 1.05$ and the world averages $\Gamma(D \to \mathrm{X}\ell^+\nu_\ell) = (0.166 \pm 0.006) \times 10^{12}\ \mathrm{s}^{-1}$ and $\tau(\Lambda_c^+) = (0.192 \pm 0.005) \times 10^{-12}$ s, we calculate $\mathrm{B}(\Lambda_c^+ \to pK^-\pi^+) = (7.3 \pm 1.4)\% \cdot f\, F$. Theoretical estimates for f and F are near 1.0 with significant uncertainties.

So, we have two results with significant model-dependence: $\mathrm{B}(\Lambda_c^+ \to pK^-\pi^+) = (4.14 \pm 0.91)\%$ from $\overline{B}$ decays, and $\mathrm{B}(\Lambda_c^+ \to pK^-\pi^+) = (7.3 \pm 1.4)\% \cdot f\, F$ from semileptonic Λ_c^+ decays. If we set $f\, F = 1.0$ in the second result, and assign an uncertainty of 30% to each result to account for the unknown model-dependence, we get the consistent results $\mathrm{B}(\Lambda_c^+ \to pK^-\pi^+) = (4.14 \pm 0.91 \pm 1.24)\%$ and $\mathrm{B}(\Lambda_c^+ \to pK^-\pi^+) = (7.3 \pm 1.4 \pm 2.2)\%$. The weighted average of these two results is $\mathrm{B}(\Lambda_c^+ \to pK^-\pi^+) = (5.0 \pm 1.3)\%$, where the uncertainty contains both the experimental uncertainty and the 30% estimate of model dependence in each result. We assigned the value $(5.0 \pm 1.3)\%$ to the $\Lambda_c^+ \to pK^-\pi^+$ branching fraction in our 2000 *Review* [1].

A third type of measurement of $\mathrm{B}(\Lambda_c^+ \to pK^-\pi^+)$ has been published by CLEO (JAFFE 00). Under the assumption that a $\overline{D}$ meson and an antiproton in opposite hemispheres is evidence for a Λ_c^+ in the hemisphere of the $\overline{p}$, the fraction of such $\overline{D}\,\overline{p}$ events with a $\Lambda_c^+ \to pK^-\pi^+$ decay can be used to determine the $\Lambda_c^+ \to pK^-\pi^+$ branching fraction. CLEO measures $\mathrm{B}(\Lambda_c^+ \to pK^-\pi^+) = (5.0 \pm 1.3)\%$, which is coincidentally exactly the same value as our PDG 00 average given above. The quoted uncertainty includes significant contributions from model-dependent effects (*e.g.,* differences between the $\overline{p}$ momentum spectrum in events with a Λ_c^+ and $\overline{p}$ in the same hemisphere, and with a $\overline{D}$ and $\overline{p}$ in opposite hemispheres; extrapolation of the Λ_c^+ and $\overline{D}$ momentum spectrum below the minimum value used for rejecting B decay products; and our limited understanding of backgrounds such as $D\overline{D}N\overline{p}$ events).

We have chosen to continue to assign the value $(5.0 \pm 1.3)\%$ to the $\Lambda_c^+ \to pK^-\pi^+$ branching fraction (given as PDG 02 below). As was noted earlier, most of the other Λ_c^+ decay modes are measured relative to this mode.

New methods for measuring the Λ_c^+ absolute branching fractions have been proposed [2,3].

0.041 ± 0.010		[2,3] ALBRECHT	92O	ARG	$e^+e^- \approx \Upsilon(4S)$
0.044 ± 0.012		[2,4] CRAWFORD	92	CLEO	e^+e^- 10.5 GeV

[1] JAFFE 00 assumes that a $\overline{D}$ meson and an antiproton in opposite hemispheres tags for a Λ_c^+ in the hemisphere of the $\overline{p}$. The fraction of such $\overline{D}p$ events with a $\Lambda_c^+ \to pK^-\pi^+$ decay then gives the $pK^-\pi^+$ branching fraction. See the paper for assumptions, caveats, etc.

[2] To extract $\Gamma(pK^-\pi^+)/\Gamma_{total}$, we use $B(\overline{B} \to \Lambda_c^+ X)\cdot B(\Lambda_c^+ \to pK^-\pi^+) = (0.28 \pm 0.06)\%$, which is the average of measurements from ARGUS (ALBRECHT 88C) and CLEO (CRAWFORD 92).

[3] ALBRECHT 92O measures $B(\overline{B} \to \Lambda_c^+ X) = (6.8 \pm 0.5 \pm 0.3)\%$.

[4] CRAWFORD 92 measures $B(\overline{B} \to \Lambda_c^+ X) = (6.4 \pm 0.8 \pm 0.8)\%$.

$\Gamma(p\overline{K}^*(892)^0)/\Gamma(pK^-\pi^+)$ Γ_3/Γ_2

Unseen decay modes of the $\overline{K}^*(892)^0$ are included.

Λ_c^+ DECAY PARAMETERS

See the note on "Baryon Decay Parameters" in the neutron Listings.

α FOR $\Lambda_c^+ \to \Lambda\pi^+$

VALUE	EVTS	DOCUMENT ID		TECN	COMMENT
−0.98±0.19 OUR AVERAGE					
$-0.94\pm0.21\pm0.12$	414	[21] BISHAI	95	CLE2	$e^+e^-\approx\Upsilon(4S)$
-0.96 ± 0.42		ALBRECHT	92	ARG	$e^+e^-\approx10.4$ GeV
$-1.1\ \pm0.4$	86	AVERY	90B	CLEO	$e^+e^-\approx10.6$ GeV

[21] BISHAI 95 actually gives $\alpha=-0.94^{+0.21}_{-0.06}{}^{+0.12}_{-0.06}$, chopping the errors at the physical limit -1.0. However, for $\alpha\approx-1.0$, some experiments should *get* unphysical values ($\alpha<-1.0$), and for averaging with other measurements such values (or errors that extend below -1.0) should *not* be chopped.

α FOR $\Lambda_c^+ \to \Sigma^+\pi^0$

$\Lambda_c(2593)^+$

$I(J^P) = 0(\frac{1}{2}^-)$ Status: ***

Seen in $\Lambda_c^+\pi^+\pi^-$ but not in $\Lambda_c^+\pi^0$, so this is indeed an excited Λ_c^+ rather than a Σ_c^+. The $\Lambda_c^+\pi^+\pi^-$ mode is largely, and perhaps entirely, $\Sigma_c\pi$, which is just at threshold; thus (assuming, as has not yet been proven, that the Σ_c has $J^P=1/2^+$) the J^P here is almost certainly $1/2^-$. This result is in accord with the theoretical expectation that this is the charm counterpart of the strange $\Lambda(1405)$.

$\Lambda_c(2593)^+$ MASS

The mass is obtained from the $\Lambda_c(2593)^+-\Lambda_c^+$ mass-difference measurements below.

$\Lambda_c(2593)^+$ DECAY MODES

$\Lambda_c^+\pi\pi$ and its submode $\Sigma_c(2455)\pi$ — the latter just barely — are the only strong decays allowed to an excited Λ_c^+ having this mass; and the submode seems to dominate.

	Mode	Fraction (Γ_i/Γ)
Γ_1	$\Lambda_c^+\pi^+\pi^-$	[a] ≈ 67 %
Γ_2	$\Sigma_c(2455)^{++}\pi^-$	24 ± 7 %
Γ_3	$\Sigma_c(2455)^0\pi^+$	24 ± 7 %
Γ_4	$\Lambda_c^+\pi^+\pi^-$ 3-body	18 ± 10 %
Γ_5	$\Lambda_c^+\pi^0$	[b] not seen
Γ_6	$\Lambda_c^+\gamma$	not seen

[a] Assuming isospin conservation, so that the other third is $\Lambda_c^+\pi^0\pi^0$.

[b] A test that the isospin is indeed 0, so that the particle is indeed a Λ_c^+.

$\Lambda_c(2765)^+$ or $\Sigma_c(2765)$

$I(J^P) = ?(?^?)$ Status: *

OMITTED FROM SUMMARY TABLE

A broad, statistically significant peak (997^{+141}_{-129} events) seen in $\Lambda_c^+\pi^+\pi^-$. However, nothing at all is known about its quantum numbers, including whether it is a Λ_c^+ or a Σ_c, or whether the width might be due to overlapping states.

$\Lambda_c(2765)^+$ MASS

The mass is obtained from the $\Lambda_c(2765)^+ - \Lambda_c^+$ mass-difference measurement below.

$\Lambda_c(2880)^+$

$I(J^P) = ?(?^?)$ Status: **

OMITTED FROM SUMMARY TABLE

A narrow, statistically significant peak (350^{+57}_{-55} events) seen in $\Lambda_c^+\pi^+\pi^-$. However, nothing is known about its quantum numbers—it could even be a Σ_c instead of a Λ_c^+—and it occurs in a mass region where several states are expected. ARTUSO 01 guesses, based on the narrow width, that it might be a $J^P = 1/2^-$ $\Lambda_{c0}'^+$, where the subscript 0 indicates that the two light quarks are in a $J^P = 0^-$ state.

$\Sigma_c(2520)$

$I(J^P) = 1(\frac{3}{2}^+)$ Status: ***

Seen in the $\Lambda_c^+\pi^\pm$ mass spectrum. The natural assignment is that this is the $J^P = 3/2^+$ excitation of the $\Sigma_c(2455)$, the charm counterpart of the $\Sigma(1385)$, but neither J nor P has been measured.

$\Sigma_c(2520)$ MASSES

The masses are obtained from the mass-difference measurements that follow.

Ξ_c^+ $I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$ Status: ***

According to the quark model, the Ξ_c^+ (quark content usc) and Ξ_c^0 form an isospin doublet, and the spin-parity ought to be $J^P = 1/2^+$. None of I, J, or P has actually been measured.

Ξ_c^+ MASS

The fit uses the Ξ_c^+ and Ξ_c^0 mass and mass-difference measurements.

VALUE (MeV)	EVTS	DOCUMENT ID		TECN	COMMENT

2460 ±25	82	BIAGI	83	SPEC	Σ^- Be 135 GeV

[1] Although COTEUS 87 claims to agree well with BIAGI 83 on the mass and width, there appears to be a discrepancy between the two experiments. BIAGI 83 sees a single peak (stated significance about 6 standard deviations) in the $\Lambda K^-\pi^+\pi^+$ mass spectrum. COTEUS 87 sees *two* peaks in the same spectrum, one at the Ξ_c^+ mass, the other 75 MeV lower. The latter is attributed to $\Xi_c^+ \to \Sigma^0 K^-\pi^+\pi^+ \to (\Lambda\gamma)K^-\pi^+\pi^+$, with the γ unseen. The *combined* significance of the double peak is stated to be 5.5 standard deviations. But the absence of any trace of a lower peak in BIAGI 83 seems to us to throw into question the interpretation of the lower peak of COTEUS 87.

Ξ_c^0

$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$ Status: ***

According to the quark model, the Ξ_c^0 (quark content dsc) and Ξ_c^+ form an isospin doublet, and the spin-parity ought to be $J^P = 1/2^+$. None of I, J, or P has actually been measured.

Ξ_c^0 MASS

The fit uses the Ξ_c^0 and Ξ_c^+ mass and mass-difference measurements.

$\Xi_c^{\prime+}$

$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$ Status: ***

The $\Xi_c^{\prime+}$ and $\Xi_c^{\prime0}$ presumably complete the SU(3) sextet whose other members are the Σ_c^{++}, Σ_c^+, Σ_c^0, and Ω_c^0: see Fig. 3 in the Note on Charmed Baryons just before the the Λ_c^+ Listings. The quantum numbers given above come from this presumption but have not been measured.

$\Xi_c^{\prime+}$ MASS

The mass is obtained from the mass-difference measurement that follows.

VALUE (MeV)	DOCUMENT ID

DOUBLY-CHARMED BARYONS ($C = +2$)

$\Xi_{cc}^{++} = ucc$, $\Xi_{cc}^{+} = dcc$, $\Omega_{cc}^{+} = scc$

Ξ_{cc}^{+}

$I(J^P) = ?(?^?)$ Status: *

OMITTED FROM SUMMARY TABLE

MATTSON 02 claims "an excess of 15.9 events over an expected background of 6.1 ± 0.5 events, a statistical significance of 6.3σ" in the $\Lambda_c^+ K^- \pi^+$ invariant-mass spectrum. The probability that the peak is a fluctuation increases from 1.0×10^{-6} to 1.1×10^{-4} when the number of bins searched is considered.

See the paper for various other tests made of the significance of the signal. Confirmation is needed before the state can be considered to be established.

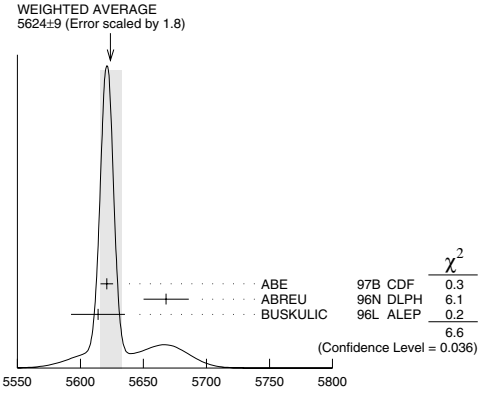
5650^{+150}_{-200}	90	BARI	91	SFM	$\Lambda_b^0 \to \Lambda_c^+\pi^+\pi^-\pi^-$

[1] ABE 97B observed 38 events above a background 18 ± 1.6 events in the mass range 5.60–5.65 GeV/c^2, a significance of > 3.4 standard deviations.

[2] Uses 4 fully reconstructed Λ_b events.

[3] ABE 93B states that, based on the signal claimed by ALBAJAR 91E, CDF should have found 30 ± 23 $\Lambda_b^0 \to J/\psi(1S)\Lambda$ events. Instead, CDF found not more than 2 events.

[4] ALBAJAR 91E claims 16 ± 5 events above a background of 9 ± 1 events, a significance of about 5 standard deviations.



Λ_b^0 MEAN LIFE

These are actually measurements of the average lifetime of weakly decaying b baryons weighted by generally unknown production rates, branching fractions, and detection efficiencies. Presumably, the mix is mainly Λ_b^0, with some Ξ_b^0 and Ξ_b^-.

See b-baryon Admixture section for data on b-baryon mean life average over species of b-baryon particles.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account corrections between the measurements and asymmetric lifetime errors.

[5] Measured using $\Lambda_c\ell^-$ and $\Lambda\ell^+\ell^-$.

Λ_b^0 DECAY MODES

These branching fractions are actually an average over weakly decaying b-baryons weighted by their production rates in Z decay (or high-energy $p\overline{p}$), branching ratios, and detection efficiencies. They scale with the LEP b-baryon production fraction $B(b \to b\text{-baryon})$ and are evaluated for our value $B(b \to b\text{-baryon}) = (9.9 \pm 1.7)\%$.

The branching fractions $B(b\text{-baryon} \to \Lambda\ell^-\overline{\nu}_\ell \text{anything})$ and $B(\Lambda_b^0 \to \Lambda_c^+\ell^-\overline{\nu}_\ell \text{anything})$ are not pure measurements because the underlying measured products of these with $B(b \to b\text{-baryon})$ were used to determine $B(b \to b\text{-baryon})$, as described in the note "Production and Decay of b-Flavored Hadrons."

For inclusive branching fractions, *e.g.*, $B \to D^\pm$ anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

Ξ_b^0, Ξ_b^-

$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$ Status: *

OMITTED FROM SUMMARY TABLE

ABREU 95V observe an excess of same-sign $\Xi^\mp \ell^\mp$ events in jets, which they interpret as $\Xi_b \to \Xi^- \ell^- \overline{\nu}_\ell$X. They find that the probability for these events to come from non-b-baryon decays is less than 5×10^{-4} and that Λ_b decays can account for less than 10% of these events.

In the quark model, Ξ_b^0 and Ξ_b^- are an isodoublet (usb, dsb) state; the lowest Ξ_b^0 and Ξ_b^- ought to have $J^P = 1/2^+$. None of I, J, or P have actually been measured.

Ξ_b MEAN LIFE

This is actually a measurement of the average lifetime of b-baryons that decay to a jet containing a same-sign $\Xi^\mp \ell^\mp$ pair. Presumably the mix is mainly Ξ_b, with some Λ_b.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account corrections between the measurements and asymmetric lifetime errors.

b-baryon ADMIXTURE (Λ_b, Ξ_b, Σ_b, Ω_b)

b-baryon ADMIXTURE MEAN LIFE

Each measurement of the b-baryon mean life is an average over an admixture of various b baryons which decay weakly. Different techniques emphasize different admixtures of produced particles, which could result in a different b-baryon mean life. More b-baryon flavor specific channels are not included in the measurement.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account corrections between the measurements and asymmetric lifetime errors.

b-baryon ADMIXTURE DECAY MODES (Λ_b, Ξ_b, Σ_b, Ω_b)

These branching fractions are actually an average over weakly decaying b-baryons weighted by their production rates in Z decay (or high-energy $p\overline{p}$), branching ratios, and detection efficiencies. They scale with the LEP b-baryon production fraction $B(b \to b\text{-baryon})$ and are evaluated for our value $B(b \to b\text{-baryon}) = (9.9 \pm 1.7)\%$.

The branching fractions $B(b\text{-baryon} \to \Lambda\ell^-\overline{\nu}_\ell \text{ anything})$ and $B(\Lambda_b^0 \to \Lambda_c^+\ell^-\overline{\nu}_\ell \text{ anything})$ are not pure measurements because the underlying measured products of these with $B(b \to b\text{-baryon})$ were used to determine $B(b \to b\text{-baryon})$, as described in the note "Production and Decay of b-Flavored Hadrons."

For inclusive branching fractions, *e.g.*, $B \to D^\pm$ anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

	Mode	Fraction (Γ_i/Γ)
Γ_1	$p\mu^-\overline{\nu}$ anything	$(4.9^{+2.1}_{-1.8})\%$
Γ_2	$p\ell\overline{\nu}_\ell$ anything	$(4.8 \pm 1.1)\%$
Γ_3	p anything	$(60 \pm 20)\%$
Γ_4	$\Lambda\ell^-\overline{\nu}_\ell$ anything	$(3.2 \pm 0.6)\%$
Γ_5	$\Lambda\ell^+\nu_\ell$ anything	
Γ_6	Λ anything	
Γ_7	$\Lambda_c^+\ell^-\overline{\nu}_\ell$ anything	
Γ_8	$\Lambda/\overline{\Lambda}$ anything	$(33 \pm 7)\%$
Γ_9	$\Xi^-\ell^-\overline{\nu}_\ell$ anything	$(5.6 \pm 1.5) \times 10^{-3}$

Magnetic Monopole Searches

MAGNETIC MONOPOLE SEARCHES

Revised December 1997 by D.E. Groom (LBNL).

"At the present time (1975) there is no experimental evidence for the existence of magnetic charges or monopoles, but chiefly because of an early, brilliant theoretical argument by Dirac, the search for monopoles is renewed whenever a new energy region is opened up in high energy physics or a new source of matter, such as rocks from the moon, becomes available [1]." Dirac argued that a monopole anywhere in the universe results in electric charge quantization everywhere, and leads to the prediction of a least magnetic charge $g = e/2\alpha$, the Dirac charge [2]. Recently monopoles have become indispensable in many gauge theories, which endow them with a variety of extraordinarily large masses. The discovery by a candidate event in a single superconducting loop in 1982 [6] stimulated an enormous experimental effort to search for supermassive magnetic monopoles [3,4,5].

Monopole detectors have predominantly used either induction or ionization. Induction experiments measure the monopole magnetic charge and are independent of monopole electric charge, mass, and velocity. Monopole candidate events in single semiconductor loops [6,7] have been detected by this method, but no two-loop coincidence has been observed. Ionization experiments rely on a magnetic charge producing more ionization than an electrical charge with the same velocity. In the case of supermassive monopoles, time-of-flight measurements indicating $v \ll c$ has also been a frequently sought signature.

Cosmic rays are the most likely source of massive monopoles, since accelerator energies are insufficient to produce them. Evidence for such monopoles may also be obtained from astrophysical observations.

Jackson's 1975 assessment remains true. The search is somewhat abated by the lack of success in the 1980's and the decrease of interest in grand unified gauge theories.

[1] KALBFLEISCH 04 reports searches for stopped magnetic monopoles in Be, Al, and Pb samples obtained from discarded material from the upgrading of DØ and CDF. A large-aperture warm-bore cryogenic detector was used. The approach was an extension of the methods of KALBFLEISCH 00. Results are model dependent.
[2] KALBFLEISCH 00 used an induction method to search for stopped monopoles in pieces of the DØ (FNAL) beryllium beam pipe and in extensions to the drift chamber aluminum support cylinder. Results are model dependent.
[3] KALBFLEISCH 00 result is for aluminum.
[4] KALBFLEISCH 00 result is for beryllium.
[5] HE 97 used a lead target and barium phosphate glass detectors. Cross-section limits are well below those predicted via the Drell-Yan mechanism.
[6] Multiphoton events.
[7] Cherenkov radiation polarization.
[8] Re-examines CERN neutrino experiments.

Monopole Production — Other Accelerator Searches

> 510			88–94	e^+e^-	[10] ACCIARRI	95C	L3

[9] ABBOTT 98K search for heavy pointlike Dirac monopoles via central production of a pair of photons with high transverse energies.
[10] ACCIARRI 95C finds a limit $B(Z \to \gamma\gamma\gamma) < 0.8 \times 10^{-5}$ (which is possible via a monopole loop) at 95% CL and sets the mass limit via a cross section model.

Monopole Flux — Cosmic Ray Searches

"Caty" in the charge column indicates a search for monopole-catalyzed nucleon decay. The absence of an entry usually means a track-etch experiment.

[11] AMBROSIO 02B direct search final result for $m\ge10^{17}$ GeV, based upon 4.2 to 9.5 years of running, depending upon the subsystem. Limit with CR39 track-etch detector extends the limit from $\beta=4\times10^{-5}$ (3.1×10^{-16} cm^{-2} sr^{-1} s^{-1}) to $\beta=1\times10^{-4}$ (2.1×10^{-16} cm^{-2} sr^{-1} s^{-1}). Limit curve in paper is piecewise continuous due to different detection techniques for different β ranges.

[12] AMBROSIO 02C limit for catalysis of nucleon decay with catalysis cross section of $\approx$ 1 mb. The flux limit increases by $\sim$ 3 at the higher β limit, and increases to 1×10^{-14} cm^{-2} sr^{-1} s^{-1} if the catalysis cross section is 0.01 mb. Based upon 71193 hr of data with the streamer detector, with an acceptance of 4250 m^2 sr.

[13] AMBROSIO 02D result for "more than two years of data." Ionization search using several subsystems. Limit curve as a function of β not given. Included in AMBROSIO 02B.

[14] AMBROSIO 97 global MACRO 90%CL is 0.78×10^{-15} at $\beta=1.1\times10^{-4}$, goes through a minimum at 0.61×10^{-15} near $\beta=(1.1–2.7)\times10^{-3}$, then rises to 0.84×10^{-15} at $\beta=0.1$. The global limit in this region is below the Parker bound at 10^{-15}. Less stringent limits are established for $4\times10^{-5}<\beta<1\times10^{-4}$. Limits set by various triggers and different subdetectors are given in the paper. All limits assume a catalysis cross section smaller than a few mb.

[15] AHLEN 94 limit for dyons extends down to β=0.9E−4 and a limit of 1.3E−14 extends to β = 0.8E−4. Also see comment by PRICE 94 and reply of BARISH 94. One loophole in the AHLEN 94 result is that in the case of monopoles catalyzing nucleon decay, relativisitic particles could veto the events. See AMBROSIO 97 for additional results.

[16] Catalysis of nucleon decay; sensitive to assumed catalysis cross section.

[17] ORITO 91 limits are functions of velocity. Lowest limits are given here.

[18] Used DKMPR mechanism and Penning effect.

[19] Assumes monopole attaches fermion nucleus.

[20] Limit from combining data of CAPLIN 86, BERMON 85, INCANDELA 84, and CABRERA 83. For a discussion of controversy about CAPLIN 86 observed event, see GUY 87. Also see SCHOUTEN 87.

[21] Based on lack of high- energy solar neutrinos from catalysis in the sun.

[22] Anomalous long-range α (^{4}He) tracks.

[23] CABRERA 82 candidate event has single Dirac charge within $\pm$5%.

[24] ALVAREZ 75, FLEISCHER 75, and FRIEDLANDER 75 explain as fragmenting nucleus. EBERHARD 75 and ROSS 76 discuss conflict with other experiments. HAGSTROM 77 reinterprets as antinucleus. PRICE 78 reassesses.

[25] Catalysis of nucleon decay.

[26] ADAMS 93 limit based on "survival and growth of a small galactic seed field" is 10^{-16} ($m/10^{17}$ GeV) cm^{-2} s^{-1} sr^{-1}. Above 10^{17} GeV, limit 10^{-16} (10^{17} GeV/m) cm^{-2} s^{-1} sr^{-1} (from requirement that monopole density does not overclose the universe) is more stringent.

[27] Re-evaluates PARKER 70 limit for GUT monopoles.

Review				

Supersymmetric Particle Searches

SUPERSYMMETRY

Revised September 2003 by H.E. Haber (Univ. of California, Santa Cruz) Part I, and by M. Schmitt (Northwestern Univ.) Part II.

This review is divided into two parts:

Supersymmetry, Part I (Theory)

I.1. Introduction
I.2. Structure of the MSSM
I.3. Parameters of the MSSM
I.4. The supersymmetric-particle sector
I.5. The Higgs sector of the MSSM
I.6. Reducing the MSSM parameter freedom
I.7. The constrained MSSMs: mSUGRA, GMSB, and SGUTs
I.8. Beyond the MSSM

Supersymmetry, Part II (Experiment)

II.1. Introduction
II.2. Common supersymmetry scenarios
II.3. Experimental issues
II.4. Supersymmetry searches in e^+e^- colliders
II.5. Supersymmetry searches at proton machines
II.6. Supersymmetry searches at HERA and fixed-target experiments
II.7. Conclusions

SUPERSYMMETRY, PART I (THEORY)

(by H.E. Haber)

I.1. Introduction: Supersymmetry (SUSY) is a generalization of the space-time symmetries of quantum field theory that transforms fermions into bosons and vice versa. It also provides a framework for the unification of particle physics and gravity [1–4], which is governed by the Planck scale, $M_{\rm P} \approx 10^{19}$ GeV (defined to be the energy scale where the gravitational interactions of elementary particles become comparable to the gauge interactions). In particular, it is possible that supersymmetry will ultimately explain the origin of the large hierarchy of energy scales from the W and Z masses to the Planck scale. The stability of this hierarchy in the presence of radiative corrections is not possible in the Standard Model, but can be maintained in supersymmetric theories.

If supersymmetry were an exact symmetry of nature, then particles and their superpartners (which differ in spin by half

a unit) would be degenerate in mass. Since this is not observed in data, supersymmetry cannot be an exact symmetry and must be broken. Nevertheless, the stability of the hierarchy of scales mentioned above can still be maintained if the supersymmetry breaking is *soft* [5] and the corresponding supersymmetry-breaking mass terms are no larger than a few TeV. (In softly-broken supersymmetry, the theory behaves like an unbroken supersymmetric theory at energy scales much larger than the size of the supersymmetry-breaking masses.) The most interesting theories of this type are theories of "low-energy" (or "weak-scale") supersymmetry, where the effective scale of supersymmetry breaking is tied to the scale of electroweak symmetry breaking [6–8]. The latter is characterized by the Standard Model Higgs vacuum expectation value, $v = 246$ GeV.

At present, there are no unambiguous experimental results that require the existence of low-energy supersymmetry. However, one tantalizing clue may be the observed unification of the three gauge couplings at an energy scale close to the Planck scale. The unification of gauge couplings does not occur in the Standard Model, but is achievable in the minimal supersymmetric extension of the Standard Model, and provides an additional motivation for seriously considering the low-energy supersymmetric framework [9]. If experimentation at future colliders uncovers evidence for supersymmetry, this would have a profound effect on the study of TeV-scale physics, and the development of a more fundamental theory of mass and symmetry-breaking phenomena in particle physics.

I.2. Structure of the MSSM: The minimal supersymmetric extension of the Standard Model (MSSM) consists of taking the Standard Model and adding the corresponding supersymmetric partners [3,10]. In addition, the MSSM contains two hypercharge $Y = \pm 1$ Higgs doublets, which is the minimal structure for the Higgs sector of an anomaly-free supersymmetric extension of the Standard Model. The supersymmetric structure of the theory also requires (at least) two Higgs doublets to generate mass for both "up"-type and "down"-type quarks (and charged leptons) [11,12]. All renormalizable supersymmetric interactions consistent with (global) B–L conservation (B =baryon number and L =lepton number) are included. Finally, the most general soft-supersymmetry-breaking terms are added [5]. To generate nonzero neutrino masses, extra structure is needed as discussed briefly in section I.8.

If supersymmetry is associated with the origin of the scale of electroweak interactions, then the mass parameters introduced by the soft-supersymmetry-breaking must be generally of order 1 TeV or below [13] (although models have been proposed in which some supersymmetric particle masses can be larger, in the range of 1–10 TeV [14]). Some lower bounds on these parameters exist due to the absence of supersymmetric-particle production at current accelerators [15]. Additional constraints arise from limits on the contributions of virtual supersymmetric particle exchange to a variety of Standard Model processes [16,17].

For example, the Standard Model global fit to precision electroweak data is quite good [18]. If all supersymmetric particle masses are significantly heavier than m_Z (in practice, masses greater than 300 GeV are sufficient [19]), then the effects of the supersymmetric particles decouple in loop-corrections to electroweak observables [20]. In this case, the Standard Model global fit to precision data and the corresponding MSSM fit yield similar results. On the other hand, regions of parameter space with light supersymmetric particle masses (just above the present day experimental limits) can in some cases generate significant one-loop corrections, resulting in a slight improvement or worsening of the overall global fit to the electroweak data depending on the choice of the MSSM parameters [21]. Thus, the precision electroweak data provide some constraints on the magnitude of the soft-supersymmetry-breaking terms.

There are a number of other low-energy measurements that are especially sensitive to the effects of new physics through virtual loops. For example, the virtual exchange of supersymmetric particles can contribute to the muon anomalous magnetic moment, $a_\mu \equiv \frac{1}{2}(g-2)_\mu$, and to the inclusive decay rate for $b \to s\gamma$. The most recent theoretical analysis of $(g-2)_\mu$ finds only a small deviation (less than two standard deviations) of the theoretical prediction from the experimentally observed value [22]. The theoretical prediction for $\Gamma(b \to s\gamma)$ agrees quite well (within the error bars) to the experimental observation [23]. In both cases, supersymmetric corrections could have generated an observable shift from the Standard Model prediction in some regions of the MSSM parameter space [23–25]. The absence of a significant deviation places interesting constraints on the low-energy supersymmetry parameters.

As a consequence of B–L invariance, the MSSM possesses a multiplicative R-parity invariance, where $R = (-1)^{3(B-L)+2S}$ for a particle of spin S [26]. Note that this implies that all the ordinary Standard Model particles have even R parity, whereas the corresponding supersymmetric partners have odd R parity. The conservation of R parity in scattering and decay processes has a crucial impact on supersymmetric phenomenology. For example, starting from an initial state involving ordinary (R-even) particles, it follows that supersymmetric particles must be produced in pairs. In general, these particles are highly unstable and decay into lighter states. However, R-parity invariance also implies that the lightest supersymmetric particle (LSP) is absolutely stable, and must eventually be produced at the end of a decay chain initiated by the decay of a heavy unstable supersymmetric particle.

In order to be consistent with cosmological constraints, a stable LSP is almost certainly electrically and color neutral [27]. (There are some model circumstances in which a colored gluino LSP is allowed [28], but we do not consider this possibility further here.) Consequently, the LSP in an R-parity-conserving theory is weakly interacting with ordinary matter, *i.e.*, it behaves like a stable heavy neutrino and will escape collider detectors without being directly observed. Thus, the canonical signature for conventional R-parity-conserving supersymmetric

theories is missing (transverse) energy, due to the escape of the LSP. Moreover, the LSP is a prime candidate for "cold dark matter" [29], a potentially important component of the non-baryonic dark matter that is required in many models of cosmology and galaxy formation [30]. Further aspects of dark matter can be found in Ref. [31].

In the MSSM, supersymmetry breaking is accomplished by including the most general renormalizable soft-supersymmetry-breaking terms consistent with the $SU(3)\times SU(2)\times U(1)$ gauge symmetry and R-parity invariance. These terms parameterize our ignorance of the fundamental mechanism of supersymmetry breaking. If supersymmetry breaking occurs spontaneously, then a massless Goldstone fermion called the *goldstino* ($\widetilde{G}$) must exist. The goldstino would then be the LSP and could play an important role in supersymmetric phenomenology [32]. However, the goldstino is a physical degree of freedom only in models of spontaneously broken global supersymmetry. If the supersymmetry is a local symmetry, then the theory must incorporate gravity; the resulting theory is called supergravity. In models of spontaneously broken supergravity, the goldstino is "absorbed" by the *gravitino* ($\widetilde{g}_{3/2}$), the spin-3/2 partner of the graviton [33]. By this super-Higgs mechanism, the goldstino is removed from the physical spectrum and the gravitino acquires a mass ($m_{3/2}$).

It is very difficult (perhaps impossible) to construct a realistic model of spontaneously-broken low-energy supersymmetry where the supersymmetry breaking arises solely as a consequence of the interactions of the particles of the MSSM. A more viable scheme posits a theory consisting of at least two distinct sectors: a "hidden" sector consisting of particles that are completely neutral with respect to the Standard Model gauge group, and a "visible" sector consisting of the particles of the MSSM. There are no renormalizable tree-level interactions between particles of the visible and hidden sectors. Supersymmetry breaking is assumed to occur in the hidden sector, and to then be transmitted to the MSSM by some mechanism. Two theoretical scenarios have been examined in detail: gravity-mediated and gauge-mediated supersymmetry breaking.

Supergravity models provide a natural mechanism for transmitting the supersymmetry breaking of the hidden sector to the particle spectrum of the MSSM. In models of *gravity-mediated* supersymmetry breaking, gravity is the messenger of supersymmetry breaking [34,35]. More precisely, supersymmetry breaking is mediated by effects of gravitational strength (suppressed by an inverse power of the Planck mass). In this scenario, the gravitino mass is of order the electroweak-symmetry-breaking scale, while its couplings are roughly gravitational in strength [1,36]. Such a gravitino would play no role in supersymmetric phenomenology at colliders.

In *gauge-mediated* supersymmetry breaking, supersymmetry breaking is transmitted to the MSSM via gauge forces. A typical structure of such models involves a hidden sector where supersymmetry is broken, a "messenger sector" consisting of particles (messengers) with $SU(3)\times SU(2)\times U(1)$ quantum numbers, and the visible sector consisting of the fields of the MSSM [37,38]. The direct coupling of the messengers to the hidden sector generates a supersymmetry breaking spectrum in the messenger sector. Finally, supersymmetry breaking is transmitted to the MSSM via the virtual exchange of the messengers. If this approach is extended to incorporate gravitational phenomena, then supergravity effects will also contribute to supersymmetry breaking. However, in models of gauge-mediated supersymmetry breaking, one usually chooses the model parameters in such a way that the virtual exchange of the messengers dominates the effects of the direct gravitational interactions between the hidden and visible sectors. In this scenario, the gravitino mass is typically in the eV to keV range, and is therefore the LSP. The helicity $\pm\frac{1}{2}$ components of $\widetilde{g}_{3/2}$ behave approximately like the goldstino; its coupling to the particles of the MSSM is significantly stronger than a coupling of gravitational strength.

During the last few years, new approaches to supersymmetry breaking have been proposed, based on theories in which the number of space dimensions is greater than three. This is not a new idea-consistent superstring theories are formulated in ten spacetime dimensions, and the associated M-theory is based in eleven spacetime dimensions [39]. Nevertheless, in all approaches considered above, the string scale and the inverse size of the extra dimensions are assumed to be at or near the Planck scale, below which an effective four spacetime dimensional broken supersymmetric field theory emerges. More recently, a number of supersymmetry-breaking mechanisms have been proposed that are inherently extra-dimensional. In some cases, the size of the extra dimensions can be significantly larger than $M_{\rm P}^{-1}$; in some cases of order $(\mathrm{TeV})^{-1}$ or even larger [40,41]. For example, in one approach, the fields of the MSSM live on some brane (a lower-dimensional manifold existing in a higher dimensional spacetime), while the sector of the theory that breaks supersymmetry lives on a second separated brane. Two examples of this approach are anomaly-mediated supersymmetry breaking of Ref. [42] and gaugino-mediated supersymmetry breaking of Ref. [43]; in both cases supersymmetry-breaking is transmitted through fields that live in the bulk (the higher dimensional space between the two branes). This setup has some features in common with both gravity-mediated and gauge-mediated supersymmetry breaking (*e.g.*, a hidden and visible sector and messengers). In another approach, one starts with a higher dimensional theory, which is compactified to four spacetime dimensions. In this approach, supersymmetry is broken by boundary conditions on the compactified space that distinguish between fermions and bosons [44](the so-called Scherk-Schwarz mechanism [45]). The phenomenology of such models can be strikingly different from the usual MSSM [46]. These approaches clearly deserve further investigation, although they will not be discussed further here.

I.3. Parameters of the MSSM: The parameters of the MSSM are conveniently described by considering separately

the supersymmetry-conserving sector and the supersymmetry-breaking sector. A careful discussion of the conventions used in defining the MSSM parameters can be found in Ref. [47]. For simplicity, consider the case of one generation of quarks, leptons, and their scalar superpartners. The parameters of the supersymmetry-conserving sector consist of: (i) gauge couplings: g_s, g, and g', corresponding to the Standard Model gauge group SU(3)×SU(2)×U(1) respectively; (ii) a supersymmetry-conserving Higgs mass parameter μ; and (iii) Higgs-fermion Yukawa coupling constants: λ_u, λ_d, and λ_e (corresponding to the coupling of one generation of quarks, leptons, and their superpartners to the Higgs bosons and higgsinos).

The supersymmetry-breaking sector contains the following set of parameters: (i) gaugino Majorana masses M_3, M_2, and M_1 associated with the SU(3), SU(2), and U(1) subgroups of the Standard Model; (ii) five scalar squared-mass parameters for the squarks and sleptons, $M^2_{\widetilde{Q}}$, $M^2_{\widetilde{U}}$, $M^2_{\widetilde{D}}$, $M^2_{\widetilde{L}}$, and $M^2_{\widetilde{E}}$ [corresponding to the five electroweak gauge multiplets, *i.e.*, superpartners of $(u,d)_L$, u^c_L, d^c_L, $(\nu,\ e^-)_L$, and e^c_L, where the superscript c indicates a charge-conjugated fermion]; (iii) Higgs-squark-squark and Higgs-slepton-slepton trilinear interaction terms, with coefficients A_u, A_d, and A_e (these are the so-called "A parameters"); and (iv) three scalar Higgs squared-mass parameters-two of which (m_1^2 and m_2^2) contribute to the diagonal Higgs squared-masses, given by $m_1^2+|\mu|^2$ and $m_2^2+|\mu|^2$, and a third which contributes to the off-diagonal Higgs squared-mass term, $m_{12}^2 \equiv B\mu$ (which defines the "B-parameter"). These three squared-mass parameters can be re-expressed in terms of the two Higgs vacuum expectation values, v_d and v_u (also called v_1 and v_2, respectively, in the literature), and one physical Higgs mass. Here, v_d (v_u) is the vacuum expectation value of the Higgs field which couples exclusively to down-type (up-type) quarks and leptons. Note that $v_d^2+v_u^2 = 4m_W^2/g^2 = (246\ \mathrm{GeV})^2$ is fixed by the W mass and the gauge coupling, whereas the ratio

$$\tan\beta = v_u/v_d \qquad (1)$$

is a free parameter of the model.

The total number of degrees of freedom of the MSSM is quite large, primarily due to the parameters of the soft-supersymmetry-breaking sector. In particular, in the case of three generations of quarks, leptons, and their superpartners, $M^2_{\widetilde{Q}}$, $M^2_{\widetilde{U}}$, $M^2_{\widetilde{D}}$, $M^2_{\widetilde{L}}$, and $M^2_{\widetilde{E}}$ are hermitian 3×3 matrices, and the A parameters are complex 3×3 matrices. In addition, M_1, M_2, M_3, B, and μ are in general complex. Finally, as in the Standard Model, the Higgs-fermion Yukawa couplings, λ_f ($f=u$, d, and e), are complex 3×3 matrices that are related to the quark and lepton mass matrices via: $M_f = \lambda_f v_f/\sqrt{2}$, where $v_e \equiv v_d$ (with v_u and v_d as defined above). However, not all these parameters are physical. Some of the MSSM parameters can be eliminated by expressing interaction eigenstates in terms of the mass eigenstates, with an appropriate redefinition of the MSSM fields to remove unphysical degrees of freedom. The analysis of Ref. [48] shows that the MSSM possesses 124 independent parameters. Of these, 18 parameters correspond to Standard Model parameters (including the QCD vacuum angle θ_{QCD}), one corresponds to a Higgs sector parameter (the analogue of the Standard Model Higgs mass), and 105 are genuinely new parameters of the model. The latter include: five real parameters and three CP-violating phases in the gaugino/higgsino sector, 21 squark and slepton masses, 36 real mixing angles to define the squark and slepton mass eigenstates, and 40 CP-violating phases that can appear in squark and slepton interactions. The most general R-parity-conserving minimal supersymmetric extension of the Standard Model (without additional theoretical assumptions) will be denoted henceforth as MSSM-124 [49].

I.4. The supersymmetric-particle sector: Consider the sector of supersymmetric particles (*sparticles*) in the MSSM. The supersymmetric partners of the gauge and Higgs bosons are fermions, whose names are obtained by appending "ino" at the end of the corresponding Standard Model particle name. The *gluino* is the color octet Majorana fermion partner of the gluon with mass $M_{\widetilde{g}} = |M_3|$. The supersymmetric partners of the electroweak gauge and Higgs bosons (the *gauginos* and *higgsinos*) can mix. As a result, the physical mass eigenstates are model-dependent linear combinations of these states, called *charginos* and *neutralinos*, which are obtained by diagonalizing the corresponding mass matrices. The chargino-mass matrix depends on M_2, μ, $\tan\beta$, and m_W [50].

The corresponding chargino-mass eigenstates are denoted by $\widetilde{\chi}_1^+$ and $\widetilde{\chi}_2^+$, with masses

$$M^2_{\widetilde{\chi}_1^+,\widetilde{\chi}_2^+} = \tfrac{1}{2}\Big\{ |\mu|^2+|M_2|^2+2m_W^2 \mp \Big[\big(|\mu|^2+|M_2|^2+2m_W^2\big)^2 - 4|\mu|^2|M_2|^2 - 4m_W^4\sin^2 2\beta + 8m_W^2\sin 2\beta\,\mathrm{Re}(\mu M_2)\Big]^{1/2}\Big\}, \qquad (2)$$

where the states are ordered such that $M_{\widetilde{\chi}_1^+} \le M_{\widetilde{\chi}_2^+}$. If CP-violating effects are neglected (in which case, M_2 and μ are real parameters), then one can choose a convention where $\tan\beta$ and M_2 are positive. (Note that the relative sign of M_2 and μ is meaningful. The sign of μ is convention-dependent; the reader is warned that both sign conventions appear in the literature.) The sign convention for μ implicit in Eq. (2) is used by the LEP collaborations [15] in their plots of exclusion contours in the M_2 vs. μ plane derived from the non-observation of $e^+e^- \to \widetilde{\chi}_1^+\widetilde{\chi}_1^-$.

The neutralino mass matrix depends on M_1, M_2, μ, $\tan\beta$, m_Z, and the weak mixing angle θ_W [50]. The corresponding neutralino eigenstates are usually denoted by $\widetilde{\chi}_i^0$ ($i=1,\ldots4$), according to the convention that $M_{\widetilde{\chi}_1^0} \le M_{\widetilde{\chi}_2^0} \le M_{\widetilde{\chi}_3^0} \le M_{\widetilde{\chi}_4^0}$. If a chargino or neutralino eigenstate approximates a particular gaugino or higgsino state, it is convenient to employ the corresponding nomenclature. Specifically, if M_1 and M_2 are small compared to m_Z and $|\mu|$, then the lightest neutralino $\widetilde{\chi}_1^0$ would be nearly a pure *photino*, $\widetilde{\gamma}$, the supersymmetric partner of the photon. If M_1 and m_Z are small compared to M_2 and $|\mu|$, then the lightest neutralino would be nearly a pure *bino*,

$\widetilde{B}$, the supersymmetric partner of the weak hypercharge gauge boson. If M_2 and m_Z are small compared to M_1 and $|\mu|$, then the lightest chargino pair and neutralino would constitute a triplet of roughly mass-degenerate pure *winos*, $\widetilde{W}^{\pm}$, and $\widetilde{W}_3^0$, the supersymmetric partners of the weak SU(2) gauge bosons. Finally, if $|\mu|$ and m_Z are small compared to M_1 and M_2, then the lightest neutralino would be nearly a pure *higgsino*. Each of the above cases leads to a strikingly different phenomenology.

The supersymmetric partners of the quarks and leptons are spin-zero bosons: the *squarks*, charged *sleptons*, and *sneutrinos*. For simplicity, only the one-generation case is illustrated below (using first-generation notation). For a given fermion f, there are two supersymmetric partners, $\widetilde{f}_L$ and $\widetilde{f}_R$, which are scalar partners of the corresponding left- and right-handed fermion. (There is no $\widetilde{\nu}_R$ in the MSSM.) However, in general, $\widetilde{f}_L$ and $\widetilde{f}_R$ are not mass-eigenstates, since there is $\widetilde{f}_L$-$\widetilde{f}_R$ mixing which is proportional in strength to the corresponding element of the scalar squared-mass matrix [51]

$$M^2_{LR} = \begin{cases} m_d(A_d - \mu\tan\beta), & \text{for "down"-type } f \\ m_u(A_u - \mu\cot\beta), & \text{for "up"-type } f, \end{cases} \qquad (3)$$

where m_d (m_u) is the mass of the appropriate "down" ("up") type quark or lepton. The signs of the A parameters are also convention-dependent; see Ref. [47]. Due to the appearance of the *fermion* mass in Eq. (3), one expects M_{LR} to be small compared to the diagonal squark and slepton masses, with the possible exception of the top-squark, since m_t is large, and the bottom-squark and tau-slepton if $\tan\beta \gg 1$.

The (diagonal) L- and R-type squark and slepton squared-masses are given by

$$\begin{aligned} M^2_{\widetilde{f}_L} &= M^2_{\widetilde{F}} + m_f^2 + (T_{3f} - e_f \sin^2\theta_W) m_Z^2 \cos 2\beta\,, \\ M^2_{\widetilde{f}_R} &= M^2_{\widetilde{R}} + m_f^2 + e_f \sin^2\theta_W m_Z^2 \cos 2\beta\,, \end{aligned} \qquad (4)$$

where $M^2_{\widetilde{F}} \equiv M^2_{\widetilde{Q}}$ [$M^2_{\widetilde{L}}$] for $\widetilde{u}_L$ and $\widetilde{d}_L$ [$\widetilde{\nu}_L$ and $\widetilde{e}_L$], and $M^2_{\widetilde{R}} \equiv M^2_{\widetilde{U}}$, $M^2_{\widetilde{D}}$, and $M^2_{\widetilde{E}}$ for $\widetilde{u}_R$, $\widetilde{d}_R$, and $\widetilde{e}_R$, respectively. In addition, $e_f = \frac{2}{3}$, $-\frac{1}{3}$, 0, -1 for $f = u$, d, ν, and e, respectively, $T_{3f} = \frac{1}{2}$ [$-\frac{1}{2}$] for up-type [down-type] squarks and sleptons, and m_f is the corresponding quark or lepton mass. Squark and slepton mass eigenstates, generically called $\widetilde{f}_1$ and $\widetilde{f}_2$ (these are linear combinations of $\widetilde{f}_L$ and $\widetilde{f}_R$), are obtained by diagonalizing the corresponding 2×2 squared-mass matrices.

In the case of three generations, the general analysis is more complicated. The scalar squared-masses [$M^2_{\widetilde{F}}$ and $M^2_{\widetilde{R}}$ in Eq. (4)], the fermion masses m_f, and the A parameters are now 3×3 matrices as noted in Section I.3. Thus, to obtain the squark and slepton mass eigenstates, one must diagonalize 6×6 mass matrices. As a result, intergenerational mixing is possible, although there are some constraints from the nonobservation of FCNC's [16,17]. In practice, because off-diagonal scalar mixing is appreciable only for the third generation, this additional complication can usually be neglected.

It should be noted that all mass formulae quoted in this section are tree-level results. One-loop corrections will modify all these results, and eventually must be included in any precision study of supersymmetric phenomenology [52].

I.5. The Higgs sector of the MSSM: Next, consider the MSSM Higgs sector [11,12,53]. Despite the large number of potential CP-violating phases among the MSSM-124 parameters, the tree-level MSSM Higgs sector is automatically CP-conserving. That is, unphysical phases can be absorbed into the definition of the Higgs fields such that $\tan\beta$ is a real parameter (conventionally chosen to be positive). Moreover, the physical neutral Higgs scalars are CP eigenstates. The model contains five physical Higgs particles: a charged Higgs boson pair ($H^{\pm}$), two CP-even neutral Higgs bosons (denoted by h^0 and H^0 where $m_h \leq m_H$), and one CP-odd neutral Higgs boson (A^0).

The properties of the Higgs sector are determined by the Higgs potential, which is made up of quadratic terms [whose squared-mass coefficients were mentioned above Eq. (1)] and quartic interaction terms whose coefficients are dimensionless couplings. The quartic interaction terms are manifestly supersymmetric at tree-level (and are modified by supersymmetry-breaking effects only at the loop level). In general, the quartic couplings arise from two sources: (i) the supersymmetric generalization of the scalar potential (the so-called "F-terms"), and (ii) interaction terms related by supersymmetry to the coupling of the scalar fields and the gauge fields, whose coefficients are proportional to the corresponding gauge couplings (the so-called "D-terms"). In the MSSM, F-term contributions to the quartic couplings are absent (although such terms may be present in extensions of the MSSM, *e.g.*, models with Higgs singlets). As a result, the strengths of the MSSM quartic Higgs interactions are fixed in terms of the gauge couplings. Due to the resulting constraint on the form of the two-Higgs-doublet scalar potential, all the tree-level MSSM Higgs-sector parameters depend only on two quantities: $\tan\beta$ [defined in Eq. (1)] and one Higgs mass (usually taken to be m_A). From these two quantities, one can predict the values of the remaining Higgs boson masses, an angle α (which measures the component of the original $Y = \pm 1$ Higgs doublet states in the physical CP-even neutral scalars), and the Higgs boson self-couplings.

When one-loop radiative corrections are incorporated, additional parameters of the supersymmetric model enter via virtual loops. The impact of these corrections can be significant [54]. For example, at tree-level, MSSM-124 predicts $m_h \leq m_Z|\cos 2\beta| \leq m_Z$ [11,12]. If this prediction were unmodified, it would be in conflict with the MSSM Higgs mass bounds obtained at LEP [55]. However, when radiative corrections are included, the light Higgs-mass upper bound may be significantly increased. The qualitative behavior of the radiative corrections can be most easily seen in the large top-squark mass limit, where in addition, both the splitting of the two diagonal entries [Eq. (4)] and the two off-diagonal entries [Eq. (3)]

of the top-squark squared-mass matrix are small in comparison to the average of the two top-squark squared-masses, $M_S^2 \equiv \frac{1}{2}(M_{\tilde{t}_1}^2 + M_{\tilde{t}_2}^2)$. In this case (assuming $m_A > m_Z$), the upper bound on the lightest CP-even Higgs mass at one-loop is approximately given by

$$m_h^2 \lesssim m_Z^2 + \frac{3g^2 m_t^4}{8\pi^2 m_W^2}\left\{\ln\left(M_S^2/m_t^2\right) + \frac{X_t^2}{M_S^2}\left(1 - \frac{X_t^2}{12M_S^2}\right)\right\}, \quad (5)$$

where $X_t \equiv A_t - \mu\cot\beta$ is the top-squark mixing factor [see Eq. (3)]. A more complete treatment of the radiative corrections [56] shows that Eq. (5) somewhat overestimates the true upper bound of m_h. These more refined computations, which incorporate renormalization group improvement and the leading two-loop contributions, yield $m_h \lesssim 130$ GeV (with an accuracy of a few GeV) for $m_t = 175$ GeV and $M_S \lesssim 2$ TeV [56].

In addition, one-loop radiative corrections can introduce CP-violating effects in the Higgs sector, which depend on some of the CP-violating phases among the MSSM-124 parameters [57]. Although these effects are more model-dependent, they can have a non-trivial impact on the Higgs searches at future colliders.

I.6. Reducing the MSSM parameter freedom: In Sections I.4 and I.5 we surveyed the parameters that comprise the MSSM-124. However in its most general form, the MSSM-124 is not a phenomenologically-viable theory over most of its parameter space. This conclusion follows from the observation that a generic point in the MSSM-124 parameter space exhibits: (i) no conservation of the separate lepton numbers L_e, L_μ, and L_τ; (ii) unsuppressed FCNC's; and (iii) new sources of CP violation that are inconsistent with the experimental bounds. For example, the MSSM contains many new sources of CP violation [58]. In particular, some combination of the complex phases of the gaugino-mass parameters, the A parameters, and μ must be less than of order 10^{-2}–10^{-3} (for a supersymmetry-breaking scale of 100 GeV) to avoid generating electric dipole moments for the neutron, electron, and atoms in conflict with observed data [59,60]. As a result of the phenomenological deficiencies listed above, almost the entire MSSM-124 parameter space is ruled out! This theory is viable only at very special "exceptional" points of the full parameter space.

The MSSM-124 is also theoretically incomplete since it provides no explanation for the origin of the supersymmetry-breaking parameters (and in particular, why these parameters should conform to the exceptional points of the parameter space mentioned above). Moreover, there is no understanding of the choice of parameters that leads to the breaking of the electroweak symmetry. What is needed ultimately is a fundamental theory of supersymmetry breaking, which would provide a rationale for some set of soft-supersymmetry breaking terms that would be consistent with the phenomenological constraints referred to above. Presumably, the number of independent parameters characterizing such a theory would be considerably less than 124.

In the absence of a fundamental theory of supersymmetry breaking, there are two general approaches for reducing the parameter freedom of MSSM-124. In the low-energy approach, an attempt is made to elucidate the nature of the exceptional points in the MSSM-124 parameter space that are phenomenologically viable. Consider the following two possible choices. First, one can assume that $M_{\tilde{Q}}^2$, $M_{\tilde{U}}^2$, $M_{\tilde{D}}^2$, $M_{\tilde{L}}^2$, $M_{\tilde{E}}^2$, and the matrix A parameters are generation-independent (horizontal universality [7,48,61]). Alternatively, one can simply require that all the aforementioned matrices are flavor diagonal in a basis where the quark and lepton mass matrices are diagonal (flavor alignment [62]). In either case, L_e, L_μ, and L_τ are separately conserved, while tree-level FCNC's are automatically absent. In both cases, the number of free parameters characterizing the MSSM is substantially less than 124. Both scenarios are phenomenologically viable, although there is no strong theoretical basis for either scenario.

In the high-energy approach, one treats the parameters of the MSSM as running parameters and imposes a particular structure on the soft-supersymmetry-breaking terms at a common high-energy scale (such as the Planck scale, M_P). Using the renormalization group equations, one can then derive the low-energy MSSM parameters. The initial conditions (at the appropriate high-energy scale) for the renormalization group equations depend on the mechanism by which supersymmetry breaking is communicated to the effective low energy theory. Examples of this scenario are provided by models of gravity-mediated and gauge-mediated supersymmetry breaking (see Section I.2). One bonus of such an approach is that one of the diagonal Higgs squared-mass parameters is typically driven negative by renormalization group evolution. Thus, electroweak symmetry breaking is generated radiatively, and the resulting electroweak symmetry-breaking scale is intimately tied to the scale of low-energy supersymmetry breaking.

One prediction of the high-energy approach that arises in most grand unified supergravity models and gauge-mediated supersymmetry-breaking models is the unification of the (tree-level) gaugino mass parameters at some high-energy scale M_X, *i.e.*,

$$M_1(M_X) = M_2(M_X) = M_3(M_X) = m_{1/2}\,. \quad (6)$$

Consequently, the effective low-energy gaugino mass parameters (at the electroweak scale) are related:

$$M_3 = (g_s^2/g^2)M_2\,, \qquad M_1 = (5g'^2/3g^2)M_2 \simeq 0.5M_2\,. \quad (7)$$

In this case, the chargino and neutralino masses and mixing angles depend only on three unknown parameters: the gluino mass, μ, and $\tan\beta$. If in addition $|\mu| \gg M_1$, m_Z, then the lightest neutralino is nearly a pure bino, an assumption often made in supersymmetric particle searches at colliders.

In a certain class of supergravity models, tree-level masses for the gauginos are absent. The gaugino mass parameters arise at one-loop and do not satisfy Eq. (7). In this case, one finds a model-independent contribution to the gaugino mass

whose origin can be traced to the super-conformal (super-Weyl) anomaly, which is common to all supergravity models [42]. This approach is called *anomaly-mediated* supersymmetry breaking. Eq. (7) is then replaced (in the one-loop approximation) by:

$$M_i \simeq \frac{b_i g_i^2}{16\pi^2} m_{3/2}\,, \tag{8}$$

where $m_{3/2}$ is the gravitino mass (assumed to be of order 1 TeV), and b_i are the coefficients of the MSSM gauge beta-functions corresponding to the corresponding U(1), SU(2) and SU(3) gauge groups: $(b_1, b_2, b_3) = (\frac{33}{5}, 1, -3)$. Eq. (8) yields $M_1 \simeq 2.8 M_2$ and $M_3 \simeq -8.3 M_2$, which implies that over most of the MSSM parameter space the lightest chargino pair and neutralino make up a nearly mass-degenerate triplet of winos. (For example, if $|\mu| \gg m_Z$, then Eq. (8) implies that $M_{\widetilde{\chi}_1^\pm} \simeq M_{\widetilde{\chi}_1^0} \simeq M_2$ [63].) The corresponding supersymmetric phenomenology differs significantly from the standard phenomenology based on Eq. (7), and is explored in detail in Ref. [64]. Anomaly-mediated supersymmetry breaking also generates (approximate) flavor-diagonal squark and slepton mass matrices. However, this yields negative squared-mass contributions for the sleptons in the MSSM. This fatal flaw may be possible to cure in approaches beyond the minimal supersymmetric model [65]. Alternatively, one may conclude that anomaly-mediation is not the sole source of supersymmetry-breaking in the slepton sector.

I.7. The constrained MSSMs: mSUGRA, GMSB, and SGUTs: One way to guarantee the absence of significant FCNC's mediated by virtual supersymmetric-particle exchange is to posit that the diagonal soft-supersymmetry-breaking scalar squared-masses are universal at some energy scale. In models of gauge-mediated supersymmetry breaking, scalar squared-masses are expected to be flavor-independent since gauge forces are flavor-blind. In the *minimal* supergravity (mSUGRA) framework [1–3], the soft-supersymmetry-breaking parameters at the Planck scale take a particularly simple form in which the scalar squared-masses and the A parameters are flavor-diagonal and universal [34]:

$$\begin{aligned}
&M^2_{\widetilde{Q}}(M_{\rm P}) = M^2_{\widetilde{U}}(M_{\rm P}) = M^2_{\widetilde{D}}(M_{\rm P}) = m_0^2 \mathbf{1}\,,\\
&M^2_{\widetilde{L}}(M_{\rm P}) = M^2_{\widetilde{E}}(M_{\rm P}) = m_0^2 \mathbf{1}\,,\\
&m_1^2(M_{\rm P}) = m_2^2(M_{\rm P}) = m_0^2\,,\\
&A_U(M_{\rm P}) = A_D(M_{\rm P}) = A_L(M_{\rm P}) = A_0 \mathbf{1}\,,
\end{aligned} \tag{9}$$

where $\mathbf{1}$ is a 3×3 identity matrix in generation space. Renormalization group evolution is then used to derive the values of the supersymmetric parameters at the low-energy (electroweak) scale. For example, to compute squark and slepton masses, one must use the *low-energy* values for $M^2_{\widetilde{F}}$ and $M^2_{\widetilde{R}}$ in Eq. (4). Through the renormalization group running with boundary conditions specified in Eq. (7) and Eq. (9), one can show that the low-energy values of $M^2_{\widetilde{F}}$ and $M^2_{\widetilde{R}}$ depend primarily on m_0^2 and $m_{1/2}^2$. A number of useful approximate analytic expressions for superpartner masses in terms of the mSUGRA parameters can be found in Ref. [66].

Clearly, in the mSUGRA approach, the MSSM-124 parameter freedom has been significantly reduced. For example, typical mSUGRA models give low-energy values for the scalar mass parameters that satisfy $M_{\widetilde{L}} \approx M_{\widetilde{E}} < M_{\widetilde{Q}} \approx M_{\widetilde{U}} \approx M_{\widetilde{D}}$, with the squark mass parameters somewhere between a factor of 1–3 larger than the slepton mass parameters (*e.g.*, see Ref. [66]). More precisely, the low-energy values of the squark mass parameters of the first two generations are roughly degenerate, while $M_{\widetilde{Q}_3}$ and $M_{\widetilde{U}_3}$ are typically reduced by a factor of 1–3 from the values of the first and second generation squark mass parameters, because of renormalization effects due to the heavy top quark mass.

As a result, one typically finds that four flavors of squarks (with two squark eigenstates per flavor) and $\widetilde{b}_R$ are nearly mass-degenerate. The $\widetilde{b}_L$ mass and the diagonal $\widetilde{t}_L$ and $\widetilde{t}_R$ masses are reduced compared to the common squark mass of the first two generations. (If $\tan\beta \gg 1$, then the pattern of third generation squark masses is somewhat altered; *e.g.*, see Ref. [67].) In addition, there are six flavors of nearly mass-degenerate sleptons (with two slepton eigenstates per flavor for the charged sleptons and one per flavor for the sneutrinos); the sleptons are expected to be somewhat lighter than the mass-degenerate squarks. Finally, third generation squark masses and tau-slepton masses are sensitive to the strength of the respective $\widetilde{f}_L$–$\widetilde{f}_R$ mixing, as discussed below Eq. (3).

Due to the implicit $m_{1/2}$ dependence in the low-energy values of $M^2_{\widetilde{Q}}$, $M^2_{\widetilde{U}}$, and $M^2_{\widetilde{D}}$, there is a tendency for the gluino in mSUGRA models to be lighter than the first- and second-generation squarks. Moreover, the LSP is typically the lightest neutralino, $\widetilde{\chi}_1^0$, which is dominated by its bino component. However, there are some regions of mSUGRA parameter space where the above conclusions do not hold. For example, one can reject those mSUGRA parameter regimes in which the LSP is a chargino. In general, if one imposes the constraints of supersymmetric particle searches and those of cosmology (say, by requiring the LSP to be a suitable dark matter candidate), one obtains significant restrictions to the mSUGRA parameter space. A recent compilation of benchmark mSUGRA points consistent with present data from particle physics and cosmology can be found in Ref. [68].

One can count the number of independent parameters in the mSUGRA framework. In addition to 18 Standard Model parameters (excluding the Higgs mass), one must specify m_0, $m_{1/2}$, A_0, and Planck-scale values for μ and B-parameters (denoted by μ_0 and B_0). In principle, A_0, B_0, and μ_0 can be complex, although in the mSUGRA approach, these parameters are taken (arbitrarily) to be real. As previously noted, renormalization group evolution is used to compute the low-energy values of the mSUGRA parameters, which then fixes all the parameters of the low-energy MSSM. In particular, the two Higgs vacuum expectation values (or equivalently, m_Z and $\tan\beta$) can be expressed as a function of the Planck-scale supergravity

parameters. The simplest procedure is to remove μ_0 and B_0 in favor of m_Z and $\tan\beta$ (the sign of μ_0 is not fixed in this process). In this case, the MSSM spectrum and its interaction strengths are determined by five parameters: m_0, A_0, $m_{1/2}$, $\tan\beta$, and the sign of μ_0, in addition to the 18 parameters of the Standard Model. However, the mSUGRA approach is probably too simplistic. Theoretical considerations suggest that the universality of Planck-scale soft-supersymmetry-breaking parameters is not generic [69]. In particular, it is easy to write down effective operators at the Planck scale that do not respect flavor universality, and it is difficult to find a theoretical principle that would forbid them.

In contrast, in gauge-mediated supersymmetry breaking, universality of the fundamental soft-supersymmetry-breaking squark and slepton squared-mass parameters is guaranteed because the supersymmetry-breaking is communicated to the sector of MSSM fields via gauge interactions. In the minimal gauge-mediated supersymmetry-breaking (GMSB) approach, there is one effective mass scale, Λ, that determines all low-energy scalar and gaugino mass parameters through loop-effects (while the resulting A parameters are suppressed). In order that the resulting superpartner masses be of order 1 TeV or less, one must have $\Lambda \sim 100$ TeV. The origin of the μ and B-parameters is quite model-dependent, and lies somewhat outside the ansatz of gauge-mediated supersymmetry breaking. The simplest models of this type are even more restrictive than mSUGRA, with two fewer degrees of freedom. However, minimal GMSB is not a fully realized model. The sector of supersymmetry-breaking dynamics can be very complex, and no complete model of gauge-mediated supersymmetry yet exists that is both simple and compelling.

It was noted in Section I.2 that the gravitino is the LSP in GMSB models. Thus, in such models, the next-to-lightest supersymmetric particle (NLSP) plays a crucial role in the phenomenology of supersymmetric particle production and decay. Note that unlike the LSP, the NLSP can be charged. In GMSB models, the most likely candidates for the NLSP are $\widetilde{\chi}^0_1$ and $\widetilde{\tau}^\pm_R$. The NLSP will decay into its superpartner plus a gravitino (*e.g.*, $\widetilde{\chi}^0_1 \to \gamma\widetilde{g}_{3/2}$, $\widetilde{\chi}^0_1 \to Z\widetilde{g}_{3/2}$ or $\widetilde{\tau}^\pm_R \to \tau^\pm\widetilde{g}_{3/2}$), with lifetimes and branching ratios that depend on the model parameters.

Different choices for the identity of the NLSP and its decay rate lead to a variety of distinctive supersymmetric phenomenologies [38,70]. For example, a long-lived $\widetilde{\chi}^0_1$-NLSP that decays outside collider detectors leads to supersymmetric decay chains with missing energy in association with leptons and/or hadronic jets (this case is indistinguishable from the canonical phenomenology of the $\widetilde{\chi}^0_1$-LSP). On the other hand, if $\widetilde{\chi}^0_1 \to \gamma\widetilde{g}_{3/2}$ is the dominant decay mode, and the decay occurs inside the detector, then nearly *all* supersymmetric particle decay chains would contain a photon. In contrast, the case of a $\widetilde{\tau}^\pm_R$-NLSP would lead either to a new long-lived charged particle (*i.e.*, the $\widetilde{\tau}^\pm_R$) or to supersymmetric particle decay chains with τ leptons.

Finally, grand unification [71] can impose additional constraints on the MSSM parameters. Perhaps one of the most compelling hints for low-energy supersymmetry is the unification of $SU(3)\times SU(2)\times U(1)$ gauge couplings predicted by models of supersymmetric grand unified theories (SGUTs) [7,9,72] (with the supersymmetry-breaking scale of order 1 TeV or below). Gauge coupling unification, which takes place at an energy scale of order 10^{16} GeV, is quite robust [73]. For example, successful unification depends weakly on the details of the theory at the unification scale. In particular, given the low-energy values of the electroweak couplings $g(m_Z)$ and $g'(m_Z)$, one can predict $\alpha_s(m_Z)$ by using the MSSM renormalization group equations to extrapolate to higher energies, and by imposing the unification condition on the three gauge couplings at some high-energy scale, $M_{\rm X}$. This procedure, which fixes $M_{\rm X}$, can be successful (*i.e.*, three running couplings will meet at a single point) only for a unique value of $\alpha_s(m_Z)$. The extrapolation depends somewhat on the low-energy supersymmetric spectrum (so-called low-energy "threshold effects"), and on the SGUT spectrum (high-energy threshold effects), which can somewhat alter the evolution of couplings. Ref. [74] summarizes the comparison of present data with the expectations of SGUTs, and shows that the measured value of $\alpha_s(m_Z)$ is in good agreement with the predictions of supersymmetric grand unification for a reasonable choice of supersymmetric threshold corrections.

Additional SGUT predictions arise through the unification of the Higgs-fermion Yukawa couplings (λ_f). There is some evidence that $\lambda_b = \lambda_\tau$ leads to good low-energy phenomenology [75], and an intriguing possibility that $\lambda_b = \lambda_\tau = \lambda_t$ may be phenomenologically viable [67,76] in the parameter regime where $\tan\beta \simeq m_t/m_b$. Finally, grand unification imposes constraints on the soft-supersymmetry-breaking parameters. For example, gaugino-mass unification leads to the relations given by Eq. (7). Diagonal squark and slepton soft-supersymmetry-breaking scalar masses may also be unified, which is analogous to the unification of Higgs-fermion Yukawa couplings.

In the absence of a fundamental theory of supersymmetry breaking, further progress will require a detailed knowledge of the supersymmetric-particle spectrum in order to determine the nature of the high-energy parameters. Of course, any of the theoretical assumptions described in this section could be wrong and must eventually be tested experimentally.

I.8. Beyond the MSSM: Non-minimal models of low-energy supersymmetry can also be constructed. One approach is to add new structure beyond the Standard Model at the TeV scale or below. The supersymmetric extension of such a theory would be a non-minimal extension of the MSSM. Possible new structures include: (i) the supersymmetric generalization of the see-saw model of neutrino masses [77,78]; (ii) an enlarged electroweak gauge group beyond $SU(2)\times U(1)$ [79]; (iii) the addition of new, possibly exotic, matter multiplets [*e.g.*, a vector-like color triplet with electric charge $\frac{1}{3}e$; such states sometimes occur as low-energy remnants in E_6 grand unification models]; and/or (iv) the addition of low-energy $SU(3)\times SU(2)\times U(1)$

singlets [80]. A possible theoretical motivation for such new structure arises from the study of phenomenologically viable string theory ground states [81].

A second approach is to retain the minimal particle content of the MSSM but remove the assumption of R-parity invariance. The most general R-parity-violating (RPV) theory involving the MSSM spectrum introduces many new parameters to both the supersymmetry-conserving and the supersymmetry-breaking sectors. Each new interaction term violates either B or L conservation. For example, consider new scalar-fermion Yukawa couplings derived from the following interactions:

$$(\lambda_L)_{pmn}\widehat{L}_p\widehat{L}_m\widehat{E}^c_n+(\lambda'_L)_{pmn}\widehat{L}_p\widehat{Q}_m\widehat{D}^c_n+(\lambda_B)_{pmn}\widehat{U}^c_p\widehat{D}^c_m\widehat{D}^c_n\,, \quad (10)$$

where p, m, and n are generation indices, and gauge group indices are suppressed. In the notation above, $\widehat{Q}$, $\widehat{U}^c$, $\widehat{D}^c$, $\widehat{L}$, and $\widehat{E}^c$ respectively represent $(u,d)_L$, u^c_L, d^c_L, $(\nu,\, e^-)_L$, and e^c_L and the corresponding superpartners. The Yukawa interactions are obtained from Eq. (10) by taking all possible combinations involving two fermions and one scalar superpartner. Note that the term in Eq. (10) proportional to λ_B violates B, while the other two terms violate L. Even if all the terms of Eq. (10) are absent, there is one more possible supersymmetric source of R-parity violation. In the notation of Eq. (10), one can add a term of the form $(\mu_L)_p\widehat{H}_u\widehat{L}_p$, where $\widehat{H}_u$ represents the $Y=1$ Higgs doublet and its higgsino superpartner. This term is the RPV generalization of the supersymmetry-conserving Higgs mass parameter μ of the MSSM, in which the $Y=-1$ Higgs/higgsino super-multiplet $\widehat{H}_d$ is replaced by the lepton/slepton super-multiplet $\widehat{L}_p$. The RPV-parameters $(\mu_L)_p$ also violate L.

Phenomenological constraints on various low-energy B- and L-violating processes can be used to derive limits on each of the coefficients $(\lambda_L)_{pmn}$, $(\lambda'_L)_{pmn}$, and $(\lambda_B)_{pmn}$ taken one at a time [82]. If more than one coefficient is simultaneously non-zero, then the limits are, in general, more complicated. All possible RPV terms cannot be simultaneously present and unsuppressed; otherwise the proton decay rate would be many orders of magnitude larger than the present experimental bound. One way to avoid proton decay is to impose B or L invariance (either one alone would suffice). Otherwise, one must accept the requirement that certain RPV coefficients must be extremely suppressed.

One particularly interesting class of RPV models is one in which B is conserved, but L is violated. It is possible to enforce baryon number conservation, while allowing for lepton number violating interactions by imposing a discrete baryon $\mathbf{Z_3}$ symmetry on the low-energy theory [83], in place of the standard $\mathbf{Z_2}$ R parity. In these models, supersymmetric phenomenology exhibits features that are quite distinct from that of the MSSM. The LSP is no longer stable, which implies that not all supersymmetric decay chains must yield missing-energy events at colliders. Both $\Delta L=1$ and $\Delta L=2$ phenomena are allowed (if L is violated), leading to neutrino masses and mixing [84], neutrinoless double-beta decay [85], sneutrino-antisneutrino mixing [78,86,87], and s-channel resonant production of the sneutrino in e^+e^- collisions [88]. Since the distinction between the Higgs and matter super-multiplets is lost, R-parity violation permits the mixing of sleptons and Higgs bosons, the mixing of neutrinos and neutralinos, and the mixing of charged leptons and charginos, leading to more complicated mass matrices and mass eigenstates than in the MSSM. Note that if $\lambda'_L \neq 0$, then squarks can behave as leptoquarks since the following processes are allowed: $e^+\overline{u}_m \to \overline{\widetilde{d}}_n \to e^+\overline{u}_m, \overline{\nu}\overline{d}_m$, and $e^+d_m \to \widetilde{u}_n \to e^+d_m$. (As above, m and n are generation labels, so that $d_2=s$, $d_3=b$, *etc.*)

Of course, R-parity-violation can also enter via the soft-supersymmetry-breaking terms, leading to an explosion of unknown parameters (well beyond the 124 of the MSSM in the most general case). As in the MSSM, one can consider constrained versions of RPV supersymmetry, in which simplified assumptions are made about the structure of the supersymmetry breaking terms at some high energy scale. Moreover, one can make additional assumptions regarding the RPV parameters. For example, in the bilinear RPV model [89], the trilinear RPV terms of Eq. (10) (and the corresponding supersymmetry-breaking "A-parameters") are absent, and the only source of R-parity violation arises from $(\mu_L)_p$ and L-violating soft-supersymmetry-breaking "B-parameters" and squared-mass terms.

With the overwhelming evidence for neutrino masses and mixing [90], it is clear that any viable supersymmetric model of fundamental particles must incorporate some form of L violation in the low-energy theory [91]. The supersymmetric generalization of the see-saw mechanism and RPV supersymmetry provide two possible frameworks for non-zero neutrino masses. For example, Ref. [92] demonstrates how one can fit both the solar and atmospheric neutrino data in the bilinear RPV supersymmetric model. In addition, experimental and theoretical constraints from collider physics also places some non-trivial restrictions on general R-parity-violating alternatives to the MSSM (see Refs. [82] and [93] for further details).

SUPERSYMMETRY, PART II (EXPERIMENT)

Revised September, 2003 by M. Schmitt (Northwestern University)

II.1. Introduction: The theoretical strong points of supersymmetry (SUSY) have motivated many searches for supersymmetric particles. Many of these have been based on the canonical missing-energy signature caused by the escape of weakly-interacting LSP's ('lightest supersymmetric particles'). Other scenarios also have been investigated, widening the range of topologies and experimental signatures in which new physics might be found. Unfortunately, no convincing evidence for the production of supersymmetric particles has been found.

Theoretical aspects of supersymmetry have been covered in Part I of this review by H.E. Haber (see also Ref. 1, 2); we use his notations and terminology.

II.2. Common supersymmetry scenarios: In the 'canonical' scenario [1], supersymmetric particles are pair-produced and decay directly or via cascades to the LSP. It follows that there are always at least two LSP's per event. If R-parity, the quantum number which distinguishes SM and SUSY particles, is conserved, the LSP is stable. For most typical choices of model parameters, the lightest neutralino is the LSP. Since the neutralino is neutral and colorless, interacting only weakly with matter, it will escape detection, giving signal events the characteristic appearance of "missing energy." In e^+e^- machines, the total visible energy and total visible momentum can be well measured. Since the electron beam energy has a very small spread, the missing energy ($E^{\rm miss} = \sqrt{s} - E^{\rm vis}$) and the missing momentum ($\vec{p}^{\ \rm miss} = -\vec{p}^{\ \rm vis}$) are well correlated with the net energy and momentum of the LSP's. In proton colliders, the distribution of the energy and longitudinal momentum of the partons (quarks and gluons inside the (anti-)protons) is very broad, so in practice only the transverse momentum is useful. It is calculated from the vector sum of energy deposits registered in the calorimetry and is called "missing transverse energy" ($\not\!\!E_T$). Collimated jets, isolated leptons or photons, and appropriate kinematic and topological cuts provide additional handles for reducing backgrounds.

The conservation of R-parity is not required in supersymmetry, however, and in some searches it is assumed that supersymmetric particles decay via interactions which violate R-parity (RPV). For the most part the production of superpartners is unchanged, but the missing-energy signature is lost. Depending on the choice of the R-parity–violating interaction, SUSY events are characterized by an excess of leptons or hadronic jets, and in many cases it is relatively easy to suppress SM backgrounds [3]. A distinction is made between "indirect" RPV, in which the LSP decays close to the interaction point but no other decays are modified, and "direct" RPV, in which the supersymmetric particles decay to SM particles, producing no LSP's. The LSP's themselves provide a visible signal by virtue or their decay to ordinary fermions. Note that the cosmological constraint which requires stable LSP's to be charge and color neutral no longer applies when there R-parity is violated.

In models assuming gauge-mediated supersymmetry breaking (GMSB) [4], the gravitino, $\widetilde{g}_{3/2}$, is a weakly-interacting fermion with a mass so small that it can be neglected when considering the event kinematics. It is the LSP, and the lightest neutralino, $\widetilde{\chi}^0_1$, decays to it radiatively, possibly with a long lifetime. With few exceptions the decays and production of other superpartners are the same as in the canonical scenario, so when the neutralino lifetime is not too long, the event topologies are augmented by the presence of energetic and isolated photons. If the lifetime is so long that the neutralino decays outside the detector, the event topologies are the same as in the canonical scenario. In some variants of this theory the right-sleptons are lighter than the lightest neutralino, and they decay to a lepton and a gravitino. The most important case of this type is the channel $\widetilde{\tau}_R \to \tau\widetilde{G}$. The lifetime of the $\widetilde{\tau}_R$ can vary over a wide range depending on model parameters, leading to new exotic signatures, including quasi-stable, heavily ionizing charged particles.

Finally, there is another phenomenologically important scenario in which the gluino $\widetilde{g}$ is assumed to be relatively light ($M_{\widetilde{g}} < 5$ GeV/c^2). Experimental evidence does not support the hypothesis, however, as discussed further in the review by H. Murayama.

II.3. Experimental issues: When given no signal for supersymmetric particles, experimenters are obliged to derive limits on their production. The most general formulation of supersymmetry is so flexible that few universal bounds can be obtained. Often more restricted forms of the theory are evoked for which predictions are more definite. The most popular of

these is minimal supergravity ('mSUGRA'). As explained in Part I of this review, parameter freedom is drastically reduced by requiring related parameters to be equal at the unification scale, M_X. Thus, the gaugino masses are equal with value $m_{1/2}$, and the slepton, squark, and Higgs masses depend on a *common* scalar mass parameter, m_0. In the individual experimental analyses, only some of these assumptions are necessary. For example, the gluino and squark searches at proton machines constrain mainly M_3 and a scalar mass parameter m_0 for the squark masses, while the chargino, neutralino, and slepton searches at e^+e^- colliders constrain M_2 and a scalar mass parameter m_0 for the slepton masses. In addition, results from the Higgs searches can be used to constrain $m_{1/2}$ and m_0 as a function of $\tan\beta$. (The full analysis involves large radiative corrections coming from squark mixing, which is where the dependence on $m_{1/2}$ and m_0 enter.) In the mSUGRA framework, all the scalar mass parameters m_0 are the same and the three gaugino mass parameters are proportional to $m_{1/2}$, so limits from squarks, sleptons, charginos, gluinos, and Higgs all can be used together to constrain the parameter space. A slightly less constrained model allows the Higgs sector to be independent of the sfermion sector, while still requiring that the scalar mass parameter m_0 is the same for sleptons and squarks and that the gaugino mass parameter $m_{1/2}$ is the same for charginos, neutralinos and gluinos. This model is called the 'constrained MSSM' (cMSSM) [5,6].

While the mSUGRA framework is convenient, it is based on several highly specific theoretical assumptions, so limits presented in this framework cannot easily be applied to other supersymmetric models. It has been possible in some instances to reduce the model dependence of experimental results by combining several searches. When model-independent results are impossible, the underlying assumptions and their consequences are (or should be) carefully delineated.

In the analysis of data from hadron collider experiments, the experimenter considers several supersymmetric processes simultaneously. In contrast to experiments at e^+e^- colliders, it does not makes sense to talk about one process at a time due to the very broad mass range spanned. This makes the utilization of some sort of organizing device, such as a constrained version of the MSSM, practically unavoidable.

II.4. Supersymmetry searches at e^+e^- colliders:

The large electron-positron collider (LEP) at CERN ran at energies ranging from the Z peak up to $\sqrt{s} = 209$ GeV/c^2. Each experiment (ALEPH, DELPHI, L3, OPAL) accumulated large data sets at a series of energies, as detailed in [7]. For the limits discussed here, the most relevant data samples include 180 pb^{-1} at 189 GeV/c^2, and 220 pb^{-1} at higher energies, of which 140 pb^{-1} was delivered above 206 GeV/c^2. Since the last edition of this review, several of the searches at the highest energies have been finalized.

Running at the Z pole, the LEP experiments and SLD at SLAC excluded many supersymmetric particles up to about half the Z mass. These limits come mainly from the comparison of the measured Z widths to SM expectations, and are relatively insensitive to the details of SUSY particle decays [8]. The data taken at higher energies allow much stronger limits to be set, although the complex interplay of masses, cross sections, and branching ratios allow for a few exceptions to simple general limits.

The main signals come from SUSY particles with charge, weak isospin, or large Yukawa couplings. The gauge fermions (charginos and neutralinos) generally are produced with large cross sections, while the scalar particles (sleptons and squarks) are suppressed near threshold by kinematic factors.

The various SUSY particles considered at LEP typically decay directly to SM particles and LSP's, so signatures consist of some combination of jets, leptons, possibly photons, and missing energy. Consequently the search criteria are geared toward a few distinct topologies. Although they may be optimized for one specific signal, they are often efficient for others. For example, acoplanar jets are expected in both $\tilde{t}_1\bar{\tilde{t}}_1$ and $\tilde{\chi}_1^0\tilde{\chi}_2^0$ production, and acoplanar leptons for both $\tilde{\ell}^+\tilde{\ell}^-$ and $\tilde{\chi}^+\tilde{\chi}^-$.

Backgrounds come mainly from three sources. First, there are the so-called 'two-photon interactions,' in which the beam electrons emit photons which combine to produce a low mass hadronic or leptonic system leaving little visible energy in the detector. Since the electrons are seldom deflected through large angles, $p_T^{\rm miss}$ is low. Second, there is difermion production, usually accompanied by large initial-state radiation induced by the Z pole, which gives events that are well balanced with respect to the beam direction. Finally, there is four-fermion production through states with one or two resonating bosons (W^+W^-, ZZ, $We\nu$, Ze^+e^-, etc.) which can give events with large $E^{\rm miss}$ and $p_T^{\rm miss}$ due to neutrinos and electrons lost down the beam pipe.

In the canonical case, $E^{\rm miss}$ and $p_T^{\rm miss}$ are large enough to eliminate most of these backgrounds. The e^+e^- initial state is well defined so searches utilize both transverse and longitudinal momentum components. It is possible to measure the missing mass ($M_{\rm miss} = \{(\sqrt{s}-E_{\rm vis})^2 - \vec{p}^{\,2}_{\rm vis}\}^{1/2}$) which is small if $p_T^{\rm miss}$ is caused by a single neutrino or an undetected electron or photon, and large when there are two massive LSP's. The four-fermion processes cannot be entirely eliminated, however, and a non-negligible irreducible background is expected. Fortunately, the uncertainties for these backgrounds are not large.

High efficiencies are easily achieved when the mass of the LSP ($M_{\rm LSP}$) is less than the parent particle ($M_{\rm parent}$) by at least 10 GeV/c^2 and greater than about 10 GeV/c^2. Difficulties arise when the mass difference $\Delta M = M_{\rm parent} - M_{\rm LSP}$ is smaller than 10 GeV/c^2 as the signal resembles background from two-photon interactions. A very light LSP is challenging also since, kinematically speaking, it plays a role similar to a neutrino, so that, for example, a signal for charginos of mass ~ 80 GeV/c^2 is difficult to distinguish from the production of W^+W^- pairs. The lower signal efficiency obtained in these two extreme cases

has been offset by the large integrated luminosities delivered, so mass limits are not degraded.

Charginos and Neutralinos: The phenomenology of charginos and neutralinos depends on their field content: they tend to be 'gaugino-like' (for $M_2 \ll |\mu|$) or 'higgsino-like' ($|\mu| \ll M_2$), with a 'mixed' field content available only for a relatively small region of parameter space. The cross section for gauginos varies with the masses of sleptons exchanged in the t-channel. In particular, chargino production can be suppressed by more than an order of magnitude for particular values of $M_{\tilde{\nu}_e}$. The gaugino branching ratios also depend on the sfermion sector. When the sfermion masses are larger than ~ 200 GeV/c^2, the chargino and neutralino branching ratios are close to those of the W and Z bosons. Enhancements of leptonic branching ratios are important when sleptons are light. Light squarks are excluded by hadron collider experiments and are not considered. Cross sections and branching ratios for higgsinos are, in contrast, insensitive to the masses of the sfermions.

In the gaugino-like region, the lightest chargino mass is driven by M_2 and the lightest neutralino mass by M_1. For many popular models (such as 'supergravity'), M_1 and M_2 unify at a GUT scale, with $M_1 \approx M_2/2$ at the electroweak scale. Consequently, the mass difference $\Delta M = M_{\tilde{\chi}^\pm} - M_{\tilde{\chi}^0_1}$ is not very small and selection efficiencies are high. However, as explained in the theoretical section of this review, this unification scheme is not required by Supersymmetry, and it is important to consider both $M_1 \approx M_2$ and $M_1 \ll M_2$. In the higgsino-like region, chargino and neutralino masses are all close to $|\mu|$, and hence, small mass differences of order 5 GeV/c^2 are typical. In the mixed region of moderate, negative μ, $\Delta M \approx M_W$, and cuts designed to reject W background lead to lower efficiencies.

Chargino masses have been excluded up to 103 GeV/c^2. However, this limit can be degraded when the sneutrino is lighter than ~ 200 GeV/c^2. Thanks to the large integrated luminosity and the combination of four experiments [7], the impact for $M_{\tilde{\nu}_e} \gtrsim 100$ GeV/c^2 is less than a GeV/c^2. The limit is also weakened when the mass difference is small ($\Delta M = M_{\tilde{\chi}^\pm} - M_{\tilde{\chi}^0_1} \lesssim 3$ GeV/c^2), as in the higgsino region; however, in this case the associated production of neutralino pairs $\tilde{\chi}^0_1\tilde{\chi}^0_2$ is large and the problem of small mass differences ($M_{\tilde{\chi}^0_2} - M_{\tilde{\chi}^0_1}$) less severe. Experimental sensitivity now extends down to mass differences of 3 GeV/c^2, corresponding to M_2 above 2 TeV/c^2.

For a summary of the interplay of chargino field content and sfermion masses, see Fig. 1.

The possibility of extremely small mass differences has been raised in several theoretical papers which propose models rather different from supergravity [9]. The DELPHI Collaboration was the first to engineer searches to cover this scenario [10], and other collaborations have followed suit [11]. For $\Delta M \sim 1$ GeV/c^2, the signal can be distinguished from two-photon background on the basis of isolated photons detected

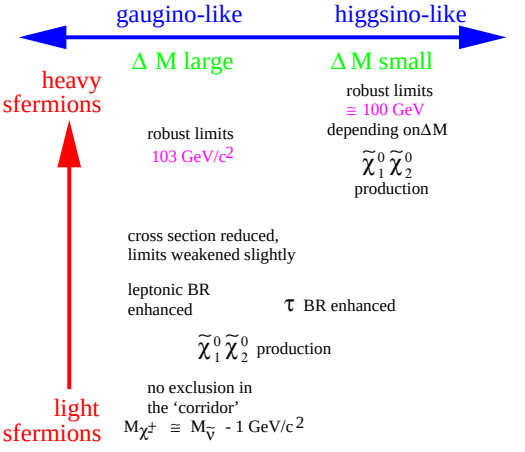

Figure 1: Heuristic diagram of the interplay of chargino field content and sfermion masses. See full-color version on color pages at end of book.

at low angles: hard initial-state radiation sometimes accompanies the signal process but is absent for the background. For $\Delta M \sim 0.2$ GeV/c^2, the chargino acquires a non-negligible lifetime and decays at a significant distance from the interaction point, producing tracks which do not extrapolate back to the interaction point. When $\Delta M < m_\pi$, the lifetime is so long that the chargino appears as a heavily ionizing particle which exits the tracking detector before decaying. The bounds on the chargino mass vary from 68 to 88 GeV/c^2 depending on the assumed sneutrino mass; the limit is 92 GeV/c^2 from the combination of the four LEP experiments when $M_{\tilde{\nu}_e} > 500$ GeV/c^2 [7].

The limits from chargino and neutralino production are most often used to constrain M_2 and μ for fixed $\tan\beta$. For large $|\mu|$ (the gaugino case), chargino bounds limit M_2, and vice versa (the Higgsino case). When $\tan\beta$ is not large, the region of parameter space with $\mu < 0$ and $|\mu| \sim M_2$ corresponds to 'mixed' field content, and the limits on M_2 and $|\mu|$ are relatively modest, especially when electron sneutrinos are light. This is the weak point when inferring an indirect limit on the LSP mass [12].

When the sleptons are light, branching ratios to leptons are enhanced, especially to τ's via $\tilde{\tau}$'s when there is non-negligible mixing of $\tilde{\tau}_R$ and $\tilde{\tau}_L$. These effects are greatest when the chargino has a large gaugino component. The weakest bounds are found for small negative μ and small $\tan\beta$, as the cross section is reduced with respect to larger $|\mu|$, the impact of $\tilde{\tau}$ mixing can be large, and the efficiency is not optimal because ΔM is large. If sneutrinos are lighter than the chargino, then two-body decays $\tilde{\chi}^+ \to \ell^+\tilde{\nu}$ dominate, and in the 'corridor' $0 < M_{\tilde{\chi}^\pm} - M_{\tilde{\nu}} \lesssim 3$ GeV/c^2 the acceptance is so low that no

direct exclusion is possible [13]. However, in the context of the cMSSM it is possible to cover this region with slepton and neutralino searches.

Sleptons: Sleptons and squarks are produced via γ^* and Z^* exchange. For selectrons there is an important contribution from t-channel neutralino exchange which generally increases the cross section. Even though the cross section is suppressed near threshold, the large luminosity at LEP has allowed mass limits to be placed close to the kinematic threshold [14]. For equal masses, the cross section for the R state is smaller than for the L state, so limits are set conservatively for the production of R-sleptons only. In grand unified theories the masses of the R and L states are linked, and usually the R state is lighter, especially when $\tan\beta$ is large. For $\tilde{\tau}$ sleptons, mixing can be important.

The simplest slepton topology results from $\tilde{\ell} \to \ell\widetilde{\chi}^0_1$, though for some particular parameter choices, branching ratios for decays to $\widetilde{\chi}^0_2$ reach a few percent. Combined mass limits have been obtained by the LEP SUSY working group [7]. For $\tilde{\mu}_R$, the limit is 95 GeV/c^2. The limit for $\tilde{e}_R$ is 4 GeV/c^2 higher due to the higher cross section coming from $\widetilde{\chi}^0$ exchange. Since the selection of τ's is relatively difficult, the limit is expected to be lower, and the actual limit is 86 GeV/c^2. These limits hold provided the slepton is at least 10 GeV/c^2 heavier than the neutralino.

Assuming a common scalar mass term m_0, as in the cMSSM, the masses of the R and L-sleptons can be related as a function of $\tan\beta$, and one finds $m_{\tilde{\ell}_L} > m_{\tilde{\ell}_R}$ by a few GeV/c^2. Consequently, in associated $\tilde{e}_L\tilde{e}_R$ production, the special case of a neutralino close in mass to the right-selectron still results in a viable signature: a single energetic electron. ALEPH and L3 have used this to close the gap $M_{\tilde{e}_R} - M_{\widetilde{\chi}} \to 0$, and place an absolute limit $M_{\widetilde{e}_R} > 73$ GeV/c^2 [15,16].

Squarks: Although the Tevatron experiments had placed general limits on squark masses far beyond the reach of LEP, a light top squark ('stop') could still have been found since the interaction eigenstates can mix to give a large splitting between the mass eigenstates. While theoretically less natural, light sbottoms also have been considered. LEP limits on stop and sbottom masses vary with the mixing angle because the cross section does: for $\theta_{\widetilde{t}} = 56°$ and $\theta_{\widetilde{b}} = 67°$ the contribution from Z exchange is "turned off." In fact the variation in mass limits is only a couple of GeV/c^2 due to the large luminosity used for these searches [7].

The stop decay $\widetilde{t}_1 \to c\widetilde{\chi}^0_1$ proceeds through loops, giving a lifetime long enough to allow the top squark to form supersymmetric hadrons which provide a pair of jets and missing energy. The conservative limit is $M_{\widetilde{t}_1} > 95$ GeV/c^2, valid for $\Delta M > 5$ GeV/c^2. If sneutrinos are light, the decay $\widetilde{t}_1 \to b\ell\widetilde{\nu}$ dominates, giving two leptons in addition to jets, and the limit is 96 GeV/c^2. The same signature obtains when sleptons are light. A somewhat more difficult case comes when $\widetilde{\tau}$'s are light [17,18,16]. Four-fermion final states ($b\,f\,\bar{f}'\,\widetilde{\chi}^0_1$) dominate when charginos are light, a topology covered by ALEPH [18]. Access to very small ΔM is possible due to the visibility of the decay products of the c and b hadrons [19], in which case conservative limit is $M_{\widetilde{t}_1} > 59$ GeV/c^2 is obtained. A comparison to results from the Tevatron is given below.

The electric charge of the sbottoms is smaller than that of stops, so the cross section is considerably lower. The only decay channel considered is $\widetilde{b}_1 \to b\widetilde{\chi}^0_1$. Use of b-jet tagging helps retain sensitivity: the bound is $M_{\widetilde{b}} > 96$ GeV/c^2. It has been pointed out that very light bottoms squarks ($M_{\widetilde{b}} < 5$ GeV/c^2) which are decoupled from the Z are not generally excluded by LEP searches. Ther is, however, a constraint from a CLEO analysis [20] applicable when the sbottoms always decay semileptonically.

The results from the search for acoplanar jets and missing energy has been interpreted as a limit on the production of generic squarks [21,16,7]. A comparison with Tevatron results is given below.

The Lightest Neutralino: In canonical SUSY scenarios the lightest neutralino leaves no signal in the detector. Nonetheless, the tight correspondences among the neutralino and chargino masses allow an indirect limit on $M_{\widetilde{\chi}^0_1}$ to be derived [12,22]. The key assumption is that the gaugino mass parameters M_1 and M_2 unify at the GUT scale, which leads to a definite relation between them at the electroweak scale: $M_1 = \frac{5}{3}\tan^2\theta_W M_2$. Assuming slepton masses to be high, the bound on $M_{\widetilde{\chi}^0_1}$ is derived from the results of chargino and neutralino searches, and the limit is $M_{\widetilde{\chi}^0_1} > 39$ GeV/c^2 [23,11].

When sleptons are lighter than ~ 200 GeV/c^2, all the effects of light sneutrinos on both the production and decay of charginos and heavier neutralinos must be taken into account. Although the bounds from charginos are weakened, useful additional constraints from slepton and higher-mass neutralino searches rule out the possibility of a light neutralino. A combined limit has been obtained in the cMSSM for any $\tan\beta$: $M_{\widetilde{\chi}^0_1} > 37$ GeV/c^2 [23]. The results of Higgs searches can be brought into play on the basis of mSUGRA mass relations, to very good effect. They exclude large regions at low m_0 and $m_{1/2}$ for low $\tan\beta$, and strengthen the neutralino bound to $M_{\widetilde{\chi}^0_1} > 45$ GeV/c^2 [7].

There is a special case for light neutralinos not excluded by collider experiments: when the $\widetilde{\chi}^0_1$ is a pure bino, the constraints from the invisible Z width and from the cross section for γ+invisible are ineffective [24]. If one does not assume any relation between M_1 and M_2 then the constraints from chargino searches can be evaded also. Thus a bino of mass $\mathcal{O}(0.1$ MeV/$c^2)$ is not excluded by collider experiments.

Gauge-Mediated Scenarios: All of the limits above obtain in supergravity models. In models with gauge-mediated supersymmetry breaking (GMSB), however, the phenomenology is rather different, and several interesting new topologies are expected. They can be classified on the basis of the 'next-to-lightest supersymmetric particle' (NLSP) which can be either

the lightest neutralino or charged sleptons, in particular, $\widetilde{\tau}_R$. The gravitino is the LSP, with mass well below a keV.

In the case in which $\widetilde{\chi}_1^0$ is the NLSP, high energy photons are present from the decay $\widetilde{\chi}_1^0 \to \gamma\,\widetilde{g}_{3/2}$. They facilitate the separation of signal and background, so for gauginos and sfermions, the resulting limits are very similar to the canonical case. The pair production of $\widetilde{\chi}_1^0$'s provides an additional search channel consisting of two acollinear photons and missing energy. The mass limit derived is 99 GeV/c^2, from ALEPH, assuming the neutralino lifetime is negligible [25]. A more general limit of 54 GeV/c^2 is set by combining searches for photons which do not point back to the interaction point with indirect limits derived from slepton and chargino searches [26]. Also, single-photon production has been used to constrain the processes $e^+e^- \to \widetilde{g}_{3/2}\widetilde{\chi}_1^0$ and $e^+e^- \to \widetilde{g}_{3/2}\widetilde{g}_{3/2}$.

When sleptons are the NLSP, there are two possibilities: all three flavors enter more or less equally, or, due to significant mixing, the lightest stau dominates. Considering first three flavors of sleptons, the topology depends strongly on the slepton lifetime which is determined by the scale parameter $\sqrt{F}$. For very short lifetimes, the decay $\widetilde{\ell}_R \to \ell\widetilde{g}_{3/2}$ corresponds to the searches described above with a very light neutralino. When the sleptons have some lifetime, the leptons will have impact parameters which help to reject backgrounds. For even longer lifetimes, the apparatus can actually resolve the decay vertex, consisting of an incoming slepton and an outgoing lepton – a track with a 'kink' in the tracking volume. Finally, if the lifetime is long, the experimental signature is a pair of collinear, heavily ionizing tracks. By combining searches for all of these signatures, limits of approximately 82 GeV/c^2 for staus can be placed independent of the slepton lifetime [27,26].

When, due to mixing, the lightest stau is significantly lighter than the other sleptons, special topologies may result. For example, 4τ final states result from neutralino pair production. No evidence for a signal was found [27,28].

R-parity Violation: If R-parity is not conserved, searches based on missing energy are not viable. The three possible RPV interaction terms ($LL\overline{E}$, $LQ\overline{D}$, $\overline{U}\,\overline{D}\,\overline{D}$) violate lepton or baryon number, consequently precisely measured SM processes constrain products of dissimilar terms. Collider searches assume only one of the many possible terms dominates; given this assumption, searches for charginos and neutralinos, sleptons and squarks have been performed. At LEP all sets of generational indices (λ_{ijk}, λ'_{ijk}, λ''_{ijk}) have been considered. Signatures of indirect and also direct RPV have been utilized. Rather exotic topologies can occur, such as six-lepton final states in slepton production with $LL\overline{E}$ dominating, or ten-jet final states in chargino production with $\overline{U}\,\overline{D}\,\overline{D}$ dominating; entirely new search criteria keyed to an excess of leptons and/or jets have been devised [29]. Searches with a wide scope have found no evidence for supersymmetry with R-parity violation, and limits are as constraining as in the canonical scenario. In fact, the direct exclusion of pair-produced $\widetilde{\chi}_1^0$'s rules out some parameter space not accessible in the canonical case.

II.5. Supersymmetry searches at hadron machines: While the LEP experiments can investigate a wide range of scenarios and cover corners of theoretical parameter space, they cannot match the mass reach of the Tevatron experiments (CDF and DØ). Although the full $p\bar{p}$ energy is never available for annihilation, the cross sections for supersymmetric particle production are large due to color factors and strong coupling. Each experiment has analyzed approximately 110 pb^{-1} of data at $\sqrt{s}$ = 1.8 TeV during Run I, which ended in 1996. Now Run IIa is underway, with an expected 2 fb^{-1} to be logged by 2006.

The main source of signals for supersymmetry are squarks and gluinos, in contradistinction to LEP. Pairs of squarks or gluinos are produced in s, t and u-channel processes. These particles decay directly or via cascades to at least two $\widetilde{\chi}_1^0$'s. The number of observed hadronic jets depends on whether the gluino or the squark is heavier, with the latter occurring naturally in mSUGRA models. The possibility of cascade decays through charginos or heavier neutralinos also enriches the possibilities of the search. The u, d, s, c, and (usually) b squarks are assumed to have similar masses; the search results are reported in terms of their average mass $M_{\widetilde{q}}$ and the gluino mass $M_{\widetilde{g}}$.

The spread of partonic energies in hadron machines is very large, so one has to consider the possible presence of several SUSY signals in one data set. A search in a given topology, such as ≥ 3 jets+$\not\!\!E_T$, can capture events from $\widetilde{q}$'s, $\widetilde{g}$'s and even $\widetilde{\chi}^{(\pm,0)}$, with or without cascade decays. Applying experimental bounds on one production mechanism while ignoring the rest would be invalid, so the experimenters must find a relatively simple way of organizing the full phenomenology. Traditionally, they have turned to mSUGRA, in part because the fundamental parameters m_0 and $m_{1/2}$ can be fairly easily related to the squark, gluino and gaugino masses which determine the event kinematics and hence the signal acceptance.

Backgrounds at the Tevatron are relatively much higher than at LEP. There are essentially two types. First, ordinary multijet events can appear to have missing energy due to measurement errors. While large mismeasurements are rare, there are very many di-jet and tri-jet 'QCD' events. This background must be estimated directly from control samples. Second, much rarer processes yield energetic neutrinos which produce a genuine missing energy signature. Examples include the production of W and Z bosons with initial-state jets, of boson pairs, and of the top quark. Estimates for these backgrounds commonly are based on theoretical cross sections, although in some analyses direct measurements are used to reduce uncertainties.

Squarks and Gluinos: The classic searches [30] rely on large missing transverse energy $\not\!\!E_T$ caused by the escaping neutralinos. Jets with high transverse energy are also required as evidence of a hard interaction; care is taken to distinguish

genuine $\not\!\!E_T$ from fluctuations in the jet energy measurement. Backgrounds from W, Z and top production can be reduced by rejecting events with identified leptons. Uncertainties in the rates of these processes can be reduced by normalizing related samples, such as events with two jets and one or more leptons. The tails of more ordinary hard-scattering processes accompanied by multiple gluon emission are estimated directly using simulations normalized using the data.

The bounds traditionally are derived for the $(M_{\tilde{g}}, M_{\tilde{q}})$ plane. The most recent analysis by the CDF Collaboration places significantly stronger bounds that previous analyses [31]. The removal of instrumental backgrounds is keyed more directly to the detector, which, together with specific topological cuts against poorly reconstructed multijet backgrounds, leaves gauge boson and $t\bar{t}$ backgrounds dominant. The estimates for these are tied directly to CDF measurements, which greatly reduces systematic uncertainties. The signal region is loosely specified by demanding high $\not\!\!E_T$ and H_T, the scalar sum of the $\not\!\!E_T$ of the second and third jets, and $\not\!\!E_T$. The number of isolated tracks allows the experimentalist to switch between a background-dominated sample and one which could contain SUSY events. As a measure of analysis rigor, the region expected to be potentially rich in SUSY events is ignored as the event counts in background-dominated samples are examined. No excess is observed, and the cuts on $\not\!\!E_T$ and H_T are tuned to obtain the exclusion shown in Fig. 2.

If squarks are heavier than gluinos, then $M_{\tilde{g}} \gtrsim 195$ GeV/c^2. If they all have the same mass, then that mass is at least 300 GeV/c^2. If the squarks are much lighter than the gluino (in which case they decay via $\tilde{q} \to q\tilde{\chi}_1^0$), the bound on the gluino mass is generally high, much more than 300 GeV/c^2. A small region in which the neutralino-squark mass difference is small, is covered by the LEP experiments (see Fig. 2).

Since these results are expressed in terms of the physical masses relevant to the production process and experimental signature, the excluded region depends primarily on the assumption of nearly equal squark masses with only a small dependence on other parameters such as μ and $\tan\beta$. Direct constraints on the theoretical parameters m_0 and $m_{1/2} \approx 0.34\, M_3$ have been obtained by DØ assuming the mass relations of the mSUGRA model (see the first paper in [30]. These bounds do not carry significantly more information than contained in the region above the diagonal of Fig. 2. It is interesting to note that, if the LEP limits on chargino production are interpreted in this context as an indirect limit on gluinos, then roughly one obtains $M_{\tilde{g}} > 310$ GeV/c^2 [6].

Gauginos: In the context of the mSUGRA model, which fixes $|\mu|$ by the requirement of radiative electroweak symmetry breaking, the lightest chargino and neutralinos are dominantly gaugino. They may be produced directly by annihilation ($q\overline{q} \to \tilde{\chi}_i^{\pm}\tilde{\chi}_j^0$) or in the decays of heavier squarks ($\tilde{q} \to q'\tilde{\chi}_i^{\pm}$, $q\tilde{\chi}_j^0$). They decay to energetic leptons ($\tilde{\chi}^{\pm} \to \ell^{\pm}\nu^{(*)}\tilde{\chi}_1^0$ and $\tilde{\chi}_2^0 \to \ell^+\ell^-\tilde{\chi}_1^0$) and the branching ratio can be high for some parameter

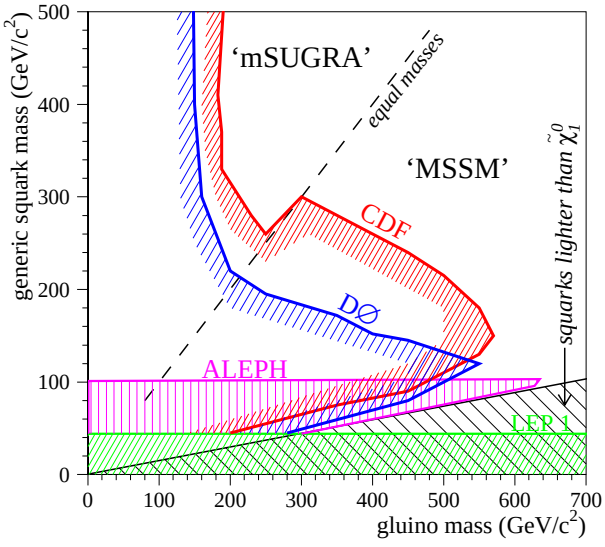

Figure 2: Regions in the $M_{\tilde{g}}$-$M_{\tilde{q}}$ plane excluded by searches for jets and missing energy at CDF, DØ, and LEP. See full-color version on color pages at end of book.

choices. The presence of energetic leptons has been exploited in two ways: the 'trilepton' signature and the 'dilepton' signature.

The search for trileptons is most effective for the associated production of $\tilde{\chi}_1^{\pm}\tilde{\chi}_2^0$ [32]. The requirement of three energetic leptons (e or μ), augmented by simple angular cuts against Drell-Yan production and cosmic rays, isolation requirements against semileptonic decays of heavy mesons, and significant $\not\!\!E_T$ reduce backgrounds to a very small level. The bounds have been derived in the context of mSUGRA models, which generally predict modest leptonic branching ratios for charginos and neutralinos. Consequently, in this framework, the results are not competitive with the LEP bounds. When $\tan\beta$ is large, final states with τ's are enhanced, and existing searches are inefficient. Nonetheless the search is completely independent of the jets+$\not\!\!E_T$ search and could be more effective in particular models with light sleptons, for example.

The dilepton signal is geared more for the production of gauginos in gluino and squark cascades [33]. Jets are required as expected from the rest of the decay chain; the leptons should be well separated from the jets in order to avoid backgrounds from heavy quark decays. Drell-Yan events are rejected with simple cuts on the relative azimuthal angle of the leptons and their transverse momentum and by a cut on $\not\!\!E_T$. The Majorana nature of the gluino can be exploited by requiring two leptons with the same charge, thereby greatly reducing the background. In this scenario limits on squarks and gluinos are comparable to those from the jets+ $\not\!\!E_T$ when couched in an mSUGRA context.

DØ tried to find squarks tagged by $\widetilde{\chi}_2^0 \to \widetilde{\chi}_1^0\gamma$, where the $\widetilde{\chi}_2^0$ appear in cascade decays [34]. The branching ratio can be large for a selected set of model parameters leading to a Higgsino-like $\widetilde{\chi}_1^0$ and a gaugino-like $\widetilde{\chi}_2^0$. DØ assumed a branching ratio of 100% to place the limits $M_{\widetilde{g}} > 240$ GeV/c^2 for heavy squarks, and $M_{\widetilde{g}} > 310$ GeV/c^2 for squarks of the same mass as the gluino.

Stops and Sbottoms: The top squark is unique among the squarks because its SM partner is so massive: large off-diagonal terms in the squared-mass matrix lead to large mixing effects and a mass eigenstate possibly much lighter than all the others. This can also happen for bottom squarks for rather special parameter choices. Hence, special analyses have been developed for $\widetilde{t}_1$'s and $\widetilde{b}_1$'s among all the squarks.

Top squarks are pair-produced with no dependence on the mixing angle, in contrast to LEP. The searches are based on two final states: $c\not{E}_T$ and $b\ell\not{E}_T$, and it is assumed that one or the other dominates. Theoretical calculations show that if chargino and slepton masses are well above $M_{\widetilde{t}_1}$, then the loop-induced FCNC decay $\widetilde{t}_1 \to c\widetilde{\chi}^0$ dominates. If $M_{\widetilde{\chi}^\pm} < M_{\widetilde{t}_1}$, then $\widetilde{t}_1 \to b\widetilde{\chi}^\pm$ is the main decay mode, and the experimenters assume $BR(\widetilde{\chi}^\pm \to \ell\nu\widetilde{\chi}^0) = BR(W \to \ell\nu)$. When charginos are heavy but $M_{\widetilde{\nu}} < M_{\widetilde{t}_1}$, leptonic final states again are favored via $\widetilde{t}_1 \to b\ell\widetilde{\nu}$. In this case the branching ratio is assumed to be 1/3 for each lepton flavor. In fact, all these channels compete, and the assumption of a 100% branching ratio is not general. Furthermore, four-body decays to $b\ell\nu\widetilde{\chi}$ should not be neglected, for which limits would be reported in the $(M_{\widetilde{t}}, M_{\widetilde{\chi}})$ plane [36].

CDF have obtained a result for the $c\not{E}_T$ final state [37]. They employed their vertex detector to select charm jets. After a lepton veto and $\not{E}_T$ requirement, this result surpasses the prior result from DØ [38]. The vertex detector was also used to tag b-quark jets for the final state $b\ell\not{E}_T$. In this case, CDF went beyond simple event counting and applied a likelihood test to the shapes of kinematic distributions. Like the first DØ result, however, this search did not exclude any signal in the channel $\widetilde{t}_1 \to b\widetilde{\chi}^\pm$, and covered a small region for $\widetilde{t}_1 \to b\ell\widetilde{\nu}$. A new result from DØ is much more performant [39] and significantly extends the parameter space excluded by LEP searches. Finally, CDF considered the possibility $t \to \widetilde{t}_1\widetilde{\chi}$ followed by $\widetilde{t}_1 \to b\widetilde{\chi}^+$ [40]. Such events would remain in the top event sample and can be discriminated using a multivariate technique. No events were found compatible with the kinematics of SUSY decays, and limits on $BR(t \to \widetilde{t}_1\widetilde{\chi})$ were derived in a fairly limited range of stop and chargino masses.

The search for light $\widetilde{b}_1 \to b\widetilde{\chi}$ follows the $\widetilde{t}_1$ search in the charm channel [37]. The CDF search tightens the requirements for a jet with heavy flavor to good effect. An earlier DØ result tagged b-jets through semileptonic decays to muons [41].

A summary of the searches for stops is shown in Fig. 3. Given the modest luminosity and small detection efficiencies, the mass reach of the Tevatron searches is impressive. New data would likely extend this reach (as would the combination of results from the two experiments). Unfortunately, the region with $M_{\widetilde{\chi}^0} > M_{\widetilde{t}_1} + 20$ GeV/c^2 will remain inaccessible in Run 2, due to the necessity of requiring a minimum missing energy in the experimental trigger.

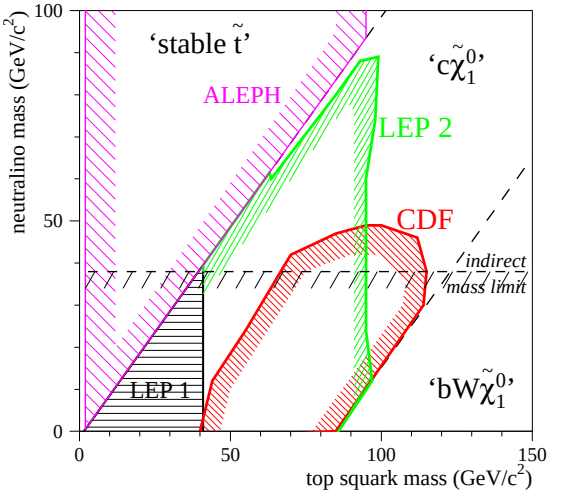

Figure 3: Regions excluded in the $(M_{\widetilde{t}_1}, M_{\widetilde{\chi}})$ plane. The results for the $c\widetilde{\chi}_1^0$ decay mode are displayed from LEP and CDF. A DELPHI result for stable stops is indicated for $M_{\widetilde{t}_1} < M_{\widetilde{\chi}}$. Finally, the indirect limit on $M_{\widetilde{\chi}}$ is also shown. There is effectively no exclusion in the region where $\widetilde{t}_1 \to bW\widetilde{\chi}_1^0$. See full-color version on color pages at end of book.

R-Parity Violation: The CDF and DØ collaborations have searched for supersymmetry in certain RPV scenarios [42] in which the lightest neutralino decays to a lepton and two quarks. DØ considered all possible production processes as a function of mSUGRA parameters. Their trilepton search amounts to strong bounds on these parameters, stronger than the limits from their search for two electrons and jets. CDF used their same-sign dielectron and jets topology to look for gluino and squark (including stop) production and obtained some specific upper limits on cross sections corresponding to $M_{\widetilde{q}} > 200$ GeV/c^2 and $M_{\widetilde{t}_1} > 120$ GeV/c^2. They also completed a search for R-parity violating stop decays, $\widetilde{t}_1 \to b\tau$ in which one tau decays leptonically and the other hadronically, giving the limit $M_{\widetilde{t}_1} > 122$ GeV/c^2 [43].

Gauge-Mediated Models: Interest in GMSB models was spurred by an anomalous '$ee\gamma\gamma\not{E}_T$' event found by the CDF Collaboration [44]. Some of these models predict large inclusive signals for $p\overline{p} \to \gamma\gamma + X$ given kinematic constraints derived from the properties of the CDF event. The photons arise from

the decay $\widetilde{\chi}_1^0 \to \gamma\widetilde{g}_{3/2}$ and the 'superlight' gravitino has a mass much smaller than the charged fermions. DØ examined their sample of $\gamma\gamma\not{E}_T$ events and reported limits on neutralino and chargino production corresponding to $M_{\widetilde{\chi}_1^0} > 75$ GeV/c^2 [45]. CDF experimenters carried out a systematic survey of events with photons and SM particles (leptons, jets, missing energy) and found no signal confirming the interpretation of the original anomalous event [44,46]. They also looked for evidence of light gravitino pairs without additional SUSY particles. The invisible gravitinos are tagged by a high-E_T jet from the initial state; this is the so-called 'monojet' signature [47]. The limit $\sqrt{F} > 215$ GeV/c^2 is placed on the fundamental parameter of this model.

DØ also reported limits on $\widetilde{q}$ and $\widetilde{g}$ production in this same scenario [35]. If $\widetilde{q}$ and $\widetilde{g}$ have similar masses, then that mass is great than 310 GeV/c^2.

In GMSB models, a heavy 'sGoldstino' is possible, which may have sizable branching ratios to photon pairs. CDF looked for narrow diphoton resonances and placed a limit $\sqrt{F} > 1$ TeV/c^2, depending on assumed mass of the sGoldstino [48].

The Search for $B_s \to \mu^+\mu^-$: Indirect evidence for SUSY could come from measurements of rare processes, especially those which are highly suppressed in the Standard Model. For example, the branching fraction for the flavor-changing neutral decay $B_s \to \mu^+\mu^-$ is only 3×10^{-9} [49]. In the MSSM, however, it can be greatly enhanced due to Higgsino and possibly gluino contributions, and in fact, $\mathcal{B}(B_s \to \mu^+\mu^-) \propto \tan^6\beta$ [50]. The exact value for the branching fraction is highly model dependent, but in mSUGRA values as high as 0.5×10^{-7} can be obtained for $\tan\beta = 55$.

CDF found no evidence for $B_s \to \mu^+\mu^-$ in their Run I data, and placed the upper limit $\mathcal{B}(B_s \to \mu^+\mu^-) < 20 \times 10^{-7}$ at 90% C.L. [51]. The sensitivity will be substantially improved for Run II due to a much higher trigger acceptance and better vertex reconstruction. Recent preliminary results from Run II have strengthened the bound to 9.5×10^{-7} (CDF, 113 pb^{-1}) and 16×10^{-7} (DØ, $\sim$ 100 pb^{-1}), both at 90% C.L. [52]. The sensitivity for an integrated luminosity of 4 fb^{-1} could reach, optimistically, 0.5×10^{-7} [53].

Table 1: Lower limits on supersymmetric particle masses. 'GMSB' refers to models with gauge-mediated supersymmetry breaking, and 'RPV' refers to models allowing R-parity violation.

particle		Condition	Lower limit (GeV/c^2)	Source
$\widetilde{\chi}_1^\pm$	gaugino	$M_{\widetilde{\nu}} > 200$ GeV/c^2	103	LEP 2
		$M_{\widetilde{\nu}} > M_{\widetilde{\chi}^\pm}$	85	LEP 2
		any $M_{\widetilde{\nu}}$	45	Z width
	Higgsino	$M_2 < 1$ TeV/c^2	99	LEP 2
	GMSB		150	DØ isolated photons
	RPV	$LL\overline{E}$ worst case	87	LEP 2
		$LQ\overline{D}$ $m_0 > 500$ GeV/c^2	88	LEP 2
$\widetilde{\chi}_1^0$	indirect	any $\tan\beta$, $M_{\widetilde{\nu}} > 500$ GeV/c^2	39	LEP 2
		any $\tan\beta$, any m_0	36	LEP 2
		any $\tan\beta$, any m_0, SUGRA Higgs	59	LEP 2 combined
	GMSB		93	LEP 2 combined
	RPV	$LL\overline{E}$ worst case	23	LEP 2
$\widetilde{e}_R$	$e\widetilde{\chi}_1^0$	$\Delta M > 10$ GeV/c^2	99	LEP 2 combined
$\widetilde{\mu}_R$	$\mu\widetilde{\chi}_1^0$	$\Delta M > 10$ GeV/c^2	95	LEP 2 combined
$\widetilde{\tau}_R$	$\tau\widetilde{\chi}_1^0$	$M_{\widetilde{\chi}_1^0} < 20$ GeV/c^2	80	LEP 2 combined
$\widetilde{\nu}$			43	Z width
$\widetilde{\mu}_R$, $\widetilde{\tau}_R$		stable	86	LEP 2 combined
$\widetilde{t}_1$	$c\widetilde{\chi}_1^0$	any $\theta_{\rm mix}$, $\Delta M > 10$ GeV/c^2	95	LEP 2 combined
		any $\theta_{\rm mix}$, $M_{\widetilde{\chi}_1^0} \sim \frac{1}{2}M_{\widetilde{t}}$	115	CDF
		any $\theta_{\rm mix}$ and any ΔM	59	ALEPH
	$b\ell\widetilde{\nu}$	any $\theta_{\rm mix}$, $\Delta M > 7$ GeV/c^2	96	LEP 2 combined
$\widetilde{g}$	any $M_{\widetilde{q}}$		195	CDF jets+$\not{E}_T$
$\widetilde{q}$	$M_{\widetilde{q}} = M_{\widetilde{g}}$		300	CDF jets+$\not{E}_T$

If the decay $B_s \to \mu^+\mu^-$ is observed, then a general lower bound on $\tan\beta$ can be derived [54]. It is also worth noting that, if a signal is observed at the Tevatron, then models based on anomaly-mediated or gauge-mediated supersymmetry breaking would not be favored [50,54].

II.7. Searches at HERA: The initial state for collisions at HERA includes an electron (or positron) and a proton, which provides a special opportunity to probe RPV scenarios with a dominant λ'_{1jk} coupling [55]. The H1 and ZEUS experiments have searched for the resonant production of squarks. The most up-to-date results include the search by H1 based on 37 pb^{-1} of e^+p data [56]. Both R_p-violating and conserving decays of the squark were covered by a combination of seven different topologies. Bounds are placed on the R_p-violating coupling as a function of the squark mass. Completely general limits on the squark mass are impossible. However, in the constrained MSSM, and assuming $M_{\widetilde{\chi}^0_1} > 30$ GeV/c^2, the limit $M_{\tilde{u}_L} > 160$ GeV/c^2 can be placed (235 GeV/c^2 for the third generation). See Ref. [56] for more details, and the Particle Listings for a list of previous results from both H1 and ZEUS.

II.8. Conclusions: A huge variety of searches for supersymmetry have been carried out at LEP, the Tevatron, and in fixed-target experiments. Despite all the effort, no inarguable signal has been found, forcing the experimenters to derive limits. We have tried to summarize the interesting cases in Table 1. At the present time there is little room for SUSY particles lighter than M_Z. The LEP collaborations have analyzed all their data, so prospects for the immediate future pass to the Tevatron collaborations. If still no sign of supersymmetry is found, definitive tests will be made at the LHC.

SUPERSYMMETRIC MODEL ASSUMPTIONS

The exclusion of particle masses within a mass range (m_1, m_2) will be denoted with the notation "none m_1–m_2" in the VALUE column of the following Listings.

Most of the results shown below, unless stated otherwise, are based on the Minimal Supersymmetric Standard Model (MSSM), as described in the Note on Supersymmetry. Unless otherwise indicated, this includes the assumption of common gaugino and scalar masses at the scale of Grand Unification (GUT), and use of the resulting relations in the spectrum and decay branching ratios. It is also assumed that R-parity (R) is conserved. Unless otherwise indicated, the results also assume that:

1) The $\widetilde{\chi}_1^0$ is the lighest supersymmetric particle (LSP)
2) $m_{\widetilde{f}_L} = m_{\widetilde{f}_R}$, where $\widetilde{f}_{L,R}$ refer to the scalar partners of left- and right-handed fermions.

Limits involving different assumptions are identified in the Comments or in the Footnotes. We summarize here the notations used in this Chapter to characterize some of the most common deviations from the MSSM (for further details, see the Note on Supersymmetry).

Theories with R-parity violation ($\not{R}$) are characterised by a superpotential of the form: $\lambda_{ijk} L_i L_j e^c_k + \lambda'_{ijk} L_i Q_j d^c_k + \lambda''_{ijk} u^c_i d^c_j d^c_k$, where i, j, k are generation indices. The presence of any of these couplings is often identified in the following by the symbols $LL\overline{E}$, $LQ\overline{D}$, and $\overline{UDD}$. Mass limits in the presence of $\not{R}$ will often refer to "direct" and "indirect" decays. Direct refers to $\not{R}$ decays of the particle in consideration. Indirect refers to cases where $\not{R}$ appears in the decays of the LSP.

In several models, most notably in theories with so-called Gauge Mediated Supersymmetry Breaking (GMSB), the gravitino ($\widetilde{G}$) is the LSP. It is usually much lighter than any other massive particle in the spectrum, and $m_{\widetilde{G}}$ is then neglected in all decay processes involving gravitinos. In these scenarios, particles other than the neutralino are sometimes considered as the next-to-lighest supersymmetric particle (NLSP), and are assumed to decay to their even-R partner plus $\widetilde{G}$. If the lifetime is short enough for the decay to take place within the detector, $\widetilde{G}$ is assumed to be undetected and to give rise to missing energy ($\not{E}$) or missing transverse energy ($\not{E}_T$) signatures.

When needed, specific assumptions on the eigenstate content of $\widetilde{\chi}^0$ and $\widetilde{\chi}^\pm$ states are indicated, using the notation $\widetilde{\gamma}$ (photino), $\widetilde{H}$ (higgsino), $\widetilde{W}$ (wino), and $\widetilde{Z}$ (zino) to signal that the limit of pure states was used. The terms gaugino is also used, to generically indicate wino-like charginos and zino-like neutralinos.

$\widetilde{\chi}_1^0$ (Lightest Neutralino) MASS LIMIT

$\widetilde{\chi}_1^0$ is often assumed to be the lightest supersymmetric particle (LSP). See also the $\widetilde{\chi}_2^0$, $\widetilde{\chi}_3^0$, $\widetilde{\chi}_4^0$ section below.

We have divided the $\widetilde{\chi}_1^0$ listings below into five sections:

1) Accelerator limits for stable $\widetilde{\chi}_1^0$,
2) Bounds on $\widetilde{\chi}_1^0$ from dark matter searches,
3) Bounds on $\widetilde{\chi}_1^0$ elastic cross sections from dark matter searches,
4) Other bounds on $\widetilde{\chi}_1^0$ from astrophysics and cosmology, and
5) Bounds on unstable $\widetilde{\chi}_1^0$.

Accelerator limits for stable $\widetilde{\chi}_1^0$

Unless otherwise stated, results in this section assume spectra, production rates, decay modes, and branching ratios as evaluated in the MSSM, with gaugino and sfermion mass unification at the GUT scale. These papers generally study production of $\widetilde{\chi}_i^0 \widetilde{\chi}_j^0$ ($i \geq 1$, $j \geq 2$), $\widetilde{\chi}_1^+ \widetilde{\chi}_1^-$, and (in the case of hadronic collisions) $\widetilde{\chi}_1^+ \widetilde{\chi}_2^0$ pairs. The mass limits on $\widetilde{\chi}_1^0$ are either direct, or follow indirectly from the constraints set by the non-observation of $\widetilde{\chi}_1^\pm$ and $\widetilde{\chi}_2^0$ states on the gaugino and higgsino MSSM parameters M_2 and μ. In some cases, information is used from the nonobservation of slepton decays.

Obsolete limits obtained from e^+e^- collisions up to $\sqrt{s}$=184 GeV have been removed from this compilation and can be found in the 2000 Edition (The European Physical Journal **C15** 1 (2000)) of this Review. $\Delta m_0 = m_{\widetilde{\chi}_2^0} - m_{\widetilde{\chi}_1^0}$.

		[6] ABBOTT	98C	D0	$p\overline{p} \rightarrow \tilde{\chi}_1^{\pm}\tilde{\chi}_2^0$
>41	95	[7] ABE	98J	CDF	$p\overline{p} \rightarrow \tilde{\chi}_1^{\pm}\tilde{\chi}_2^0$

[1] ABDALLAH 03M uses data from $\sqrt{s}$ = 192–208 GeV. A limit on the mass of $\tilde{\chi}_1^0$ is derived from direct searches for neutralinos combined with the chargino search. Neutralinos are searched in the production of $\tilde{\chi}_1^0\tilde{\chi}_2^0$, $\tilde{\chi}_1^0\tilde{\chi}_3^0$, as well as $\tilde{\chi}_2^0\tilde{\chi}_3^0$ and $\tilde{\chi}_2^0\tilde{\chi}_4^0$ giving rise to cascade decays, and $\tilde{\chi}_1^0\tilde{\chi}_2^0$ and $\tilde{\chi}_1^0\tilde{\chi}_2^0$, followed by the decay $\tilde{\chi}_2^0 \rightarrow \tilde{\tau}\tau$. The results hold for the parameter space defined by values of $M_2 < 1$ TeV, $|\mu| \leq 2$ TeV with the $\tilde{\chi}_1^0$ as LSP. The limit is obtained for tanβ = 1 and large m_0, where $\tilde{\chi}_2^0\tilde{\chi}_4^0$ and chargino pair production are important. If the constraint from Higgs searches is also imposed, the limit improves to 49.0 GeV in the M_h^{max} scenario with m_t=174.3 GeV. These limits update the results of ABREU 00J.

[2] ABDALLAH 03M uses data from $\sqrt{s}$ = 192–208 GeV. An indirect limit on the mass of $\tilde{\chi}_1^0$ is derived by constraining the MSSM parameter space by the results from direct searches for neutralinos (including cascade decays and $\tilde{\tau}\tau$ final states), for charginos (for all $\Delta m_{\pm}$) and for sleptons, stop and sbottom. The results hold for the full parameter space defined by values of $M_2 < 1$ TeV, $|\mu| \leq 2$ TeV with the $\tilde{\chi}_1^0$ as LSP. Constraints from the Higgs search in the M_h^{max} scenario assuming m_t=174.3 GeV are included. The limit is obtained for tanβ ≥5 when stau mixing leads to mass degeneracy between $\tilde{\tau}_1$ and $\tilde{\chi}_1^0$ and the limit is based on $\tilde{\chi}_2^0$ production followed by its decay to $\tilde{\tau}_1\tau$. In the pathological scenario where m_0 and $|\mu|$ are large, so that the $\tilde{\chi}_2^0$ production cross section is negligible, and where there is mixing in the stau sector but not in stop nor sbottom, the limit is based on charginos with soft decay products and an ISR photon. The limit then degrades to 39 GeV. See Figs 40–42 for the dependence of the limit on tanβ and $m_{\tilde{\nu}}$. These limits update the results of ABREU 00W.

[3] BARATE 01 data collected at 189 to 202 GeV. Updates earlier analyses of sleptons and squarks from BARATE 99Q, and of charginos and neutralinos from BARATE 98X and BARATE 99P. The limit is based on the direct search for charginos and neutralinos and the constraints from the slepton search and Z^0 width measurements, as discussed in BARATE 99P, assuming a negligible mixing in the stau sector. The limit improves to 48 GeV under the assumption of MSUGRA with unification of the Higgs and sfermion masses, when direct constraints on the Higgs mass from BARATE 01C are used and $m_{\tilde{\tau}} - m_{\tilde{\chi}_1^0} > 5$ GeV to avoid degeneracy at large tanβ. These limits include and update the results of BARATE 99P.

[4] ABBIENDI 00H data collected at $\sqrt{s}$=189 GeV. The results hold over the full parameter space defined by $0 \leq M_2 \leq 2$ TeV, $|\mu| \leq 500$ GeV, $m_0 \leq 500$ GeV, $A = \pm M_2, \pm m_0$, and 0. The minimum mass limit is reached for tanβ=1. The results of ABBIENDI 99F are used to constrain regions of parameter space dominated by radiative $\tilde{\chi}_2^0 \rightarrow \tilde{\chi}_1^0\gamma$ decays. The limit improves to 48.5 GeV for m_0=500 GeV and tanβ=35. See their Table and Figs 4–5 for the tanβ and m_0 dependence of the limits. Updates ABBIENDI 99G.

[5] ACCIARRI 00D data collected at $\sqrt{s}$=189 GeV. The results hold over the full parameter space defined by $0.7 \leq \tan\beta \leq 60$, $0 \leq M_2 \leq 2$ TeV, $m_0 \leq 500$ GeV, $|\mu| \leq 2$ TeV The minimum mass limit is reached for tanβ=1 and large m_0. The results of slepton searches from ACCIARRI 99W are used to help set constraints in the region of small m_0. The limit improves to 48 GeV for $m_0 \gtrsim 200$ GeV and tanβ $\gtrsim$ 10. See their Figs. 6–8 for the tanβ and m_0 dependence of the limits. Updates ACCIARRI 98F.

[6] ABBOTT 98C searches for trilepton final states (ℓ=e,μ). See footnote to ABBOTT 98C in the Chargino Section for details on the assumptions. Assuming a negligible decay rate of $\tilde{\chi}_1^{\pm}$ and $\tilde{\chi}_2^0$ to quarks, they obtain $m_{\tilde{\chi}_2^0} \gtrsim 51$ GeV.

[7] ABE 98J searches for trilepton final states (ℓ=e,μ). See footnote to ABE 98J in the Chargino Section for details on the assumptions. The quoted result corresponds to the best limit within the selected range of parameters, obtained for $m_{\tilde{q}} > m_{\tilde{g}}$, tanβ=2, and μ=− 600 GeV.

Bounds on $\tilde{\chi}_1^0$ from dark matter searches

These papers generally exclude regions in the $M_2-\mu$ parameter plane assuming that $\tilde{\chi}_1^0$ is the dominant form of dark matter in the galactic halo. These limits are based on the lack of detection in laboratory experiments or by the absence of a signal in underground neutrino detectors. The latter signal is expected if $\tilde{\chi}_1^0$ accumulates in the Sun or the Earth and annihilates into high-energy ν's.

none 4–15 GeV	[16] OLIVE	88	COSM

[8] AMBROSIO 99 set new neutrino flux limits which can be used to limit the parameter space in supersymmetric models based on neutralino annihilation in the Sun and the Earth.

[9] LOSECCO 95 reanalyzed the IMB data and places lower limit on $m_{\tilde{\chi}_1^0}$ of 18 GeV if the LSP is a photino and 10 GeV if the LSP is a higgsino based on LSP annihilation in the sun producing high-energy neutrinos and the limits on neutrino fluxes from the IMB detector.

[10] MORI 93 excludes some region in $M_2-\mu$ parameter space depending on tanβ and lightest scalar Higgs mass for neutralino dark matter $m_{\tilde{\chi}^0} > m_{W^{\pm}}$, using limits on upgoing muons produced by energetic neutrinos from neutralino annihilation in the Sun and the Earth.

[11] BOTTINO 92 excludes some region $M_2-\mu$ parameter space assuming that the lightest neutralino is the dark matter, using upgoing muons at Kamiokande, direct searches by Ge detectors, and by LEP experiments. The analysis includes top radiative corrections on Higgs parameters and employs two different hypotheses for nucleon-Higgs coupling. Effects of rescaling in the local neutralino density according to the neutralino relic abundance are taken into account.

[12] BOTTINO 91 excluded a region in $M_2-\mu$ plane using upgoing muon data from Kamioka experiment, assuming that the dark matter surrounding us is composed of neutralinos and that the Higgs boson is not too heavy.

[13] GELMINI 91 exclude a region in $M_2-\mu$ plane using dark matter searches.

[14] KAMIONKOWSKI 91 excludes a region in the $M_2-\mu$ plane using IMB limit on upgoing muons originated by energetic neutrinos from neutralino annihilation in the sun, assuming that the dark matter is composed of neutralinos and that $m_{H_1^0} \lesssim 50$ GeV. See Fig. 8 in the paper.

[15] MORI 91B exclude a part of the region in the $M_2-\mu$ plane with $m_{\tilde{\chi}_1^0} \lesssim 80$ GeV using a limit on upgoing muons originated by energetic neutrinos from neutralino annihilation in the earth, assuming that the dark matter surrounding us is composed of neutralinos and that $m_{H_1^0} \lesssim 80$ GeV.

[16] OLIVE 88 result assumes that photinos make up the dark matter in the galactic halo. Limit is based on annihilations in the sun and is due to an absence of high energy neutrinos detected in underground experiments. The limit is model dependent.

$\tilde{\chi}_1^0$-p elastic cross section

Experimental results on the $\tilde{\chi}_1^0$-p elastic cross section are evaluated at $m_{\tilde{\chi}_1^0}$=100 GeV. The experimental results on the cross section are often mass dependent. Therefore, the mass and cross section results are also given where the limit is strongest, when appropriate. Results are quoted separately for spin-dependent interactions (based on an effective 4-Fermi Lagrangian of the form $\overline{\chi}\gamma^{\mu}\gamma^5\chi\overline{q}\gamma_{\mu}\gamma^5 q$) and spin-independent interactions ($\overline{\chi}\chi\overline{q}q$). For calculational details see GRIEST 88B, ELLIS 88D, BARBIERI 89C, DREES 93B, ARNOWITT 96, BERGSTROM 96, and BAER 97 in addition to the theory papers listed in the Tables. For a description of the theoretical assumptions and experimental techniques underlying most of the listed papers, see the review on "Dark matter" in this "Review of Particle Properties," and references therein. Most of the following papers use galactic halo and nuclear interaction assumptions from (LEWIN 96).

[25] The strongest upper limit is 1.8×10^{-5} pb and occurs at $m_\chi \approx 80$ GeV.

[26] The strongest upper limit is 7×10^{-6} pb and occurs at $m_\chi \simeq 30$ GeV.

[27] ABRAMS 02 is incompatible with the DAMA most likely value at the 99.9% CL. The strongest upper limit is 3×10^{-6} pb and occurs at $m_\chi \simeq 30$ GeV.

[28] BENOIT 02 excludes the central result of DAMA at the 99.8%CL.

[29] The strongest upper limit is 2×10^{-5} pb and occurs at $m_\chi \simeq 40$ GeV.

[30] The strongest upper limit is 7×10^{-6} pb and occurs at $m_\chi \simeq 46$ GeV.

[31] The strongest upper limit is 1.8×10^{-5} pb and occurs at $m_\chi \simeq 32$ GeV

[32] BOTTINO 01 calculates the χ-p elastic scattering cross section in the framework of the following supersymmetric models: N=1 supergravity with the radiative breaking of the electroweak gauge symmetry, N=1 supergravity with nonuniversal scalar masses and an effective MSSM model at the electroweak scale.

[33] Calculates the χ-p elastic scattering cross section in the framework of N=1 supergravity models with radiative breaking of the electroweak gauge symmetry.

[34] ELLIS 01C calculates the χ-p elastic scattering cross section in the framework of N=1 supergravity models with radiative breaking of the electroweak gauge symmetry. ELLIS 02B find a range 2×10^{-8}–1.5×10^{-7} at $\tan\beta$=50. In models with nonuniversal Higgs masses, the upper limit to the cross section is 4×10^{-7}.

[35] ACCOMANDO 00 calculate the χ-p elastic scattering cross section in the framework of minimal N=1 supergravity models with radiative breaking of the electroweak gauge symmetry. The limit is relaxed by at least an order of magnitude when models with nonuniversal scalar masses are considered. A subset of the authors in ARNOWITT 02 updated the limit to $< 9 \times 10^{-8}$ ($\tan\beta < 55$).

[36] BERNABEI 00 search for annual modulation of the WIMP signal. The data favor the hypothesis of annual modulation at 4σ and are consistent, for a particular model framework quoted there, with m_{χ^0}=44 $^{+12}_{-9}$ GeV and a spin-independent χ^0-proton cross section of $(5.4 \pm 1.0) \times 10^{-6}$ pb. See also BERNABEI 01 and BERNABEI 00C.

[37] FENG 00 calculate the χ-p elastic scattering cross section in the framework of N=1 supergravity models with radiative breaking of the electroweak gauge symmetry with a particular emphasis on focus point models. At $\tan\beta$=50, the range is 8×10^{-8}–4×10^{-7}.

[38] BERNABEI 99 search for annual modulation of the WIMP signal. The data favor the hypothesis of annual modulation at 99.6%CL and are consistent, for the particular model framework considered there, with m_{χ^0}=59 $^{+17}_{-14}$ GeV and spin-independent χ^0-proton cross section of $(7.0^{+0.4}_{-1.2}) \times 10^{-6}$ pb (1 σ errors).

[39] BERNABEI 98 search for annual modulation of the WIMP signal. The data are consistent, for the particular model framework considered there, with m_{χ^0}=59 $^{+36}_{-19}$ GeV and spin-independent χ^0-proton cross section of $(1.0^{+0.1}_{-0.4}) \times 10^{-5}$ pb (1 σ errors).

Other bounds on $\tilde{\chi}_1^0$ from astrophysics and cosmology

Most of these papers generally exclude regions in the $M_2 - \mu$ parameter plane by requiring that the $\tilde{\chi}_1^0$ contribution to the overall cosmological density is less than some maximal value to avoid overclosure of the Universe. Those not based on the cosmological density are indicated. Many of these papers also include LEP and/or other bounds.

[40] ELLIS 00 updates ELLIS 98. Uses LEP e^+e^- data at $\sqrt{s}$=202 and 204 GeV to improve bound on neutralino mass to 51 GeV when scalar mass universality is assumed and 46 GeV when Higgs mass universality is relaxed. Limits on $\tan\beta$ improve to > 2.7 ($\mu > 0$), > 2.2 ($\mu < 0$) when scalar mass universality is assumed and > 1.9 (both signs of μ) when Higgs mass universality is relaxed.

[41] BAER 03, CHATTOPADHYAY 03, ELLIS 03C and LAHANAS 03 place constraints on the SUSY parameter space in the framework of N=1 supergravity models with radiative breaking of the electroweak gauge symmetry based on WMAP results for the cold dark matter density.

[42] BOTTINO 03 (see also BOTTINO 03A) and HOOPER 03 do not assume gaugino or scalar mass unification.

[43] BOEHM 00B and ELLIS 03 place constraints on the SUSY parameter space in the framework of minimal N=1 supergravity models with radiative breaking of the electroweak gauge symmetry. Includes the effect of χ-$\tilde{t}$ co-annihilations.

[44] BEREZINSKY 95 and ELLIS 03B places constraints on the SUSY parameter space in the framework of N=1 supergravity models with radiative breaking of the electroweak gauge symmetry but non-Universal Higgs masses.

[45] ELLIS 03D places constraints on the SUSY parameter space in the framework of N=1 supergravity models with radiative breaking of the electroweak gauge symmetry including supersymmetry breaking relations between A and B parameters.

[46] DJOUADI 01, ROSZKOWSKI 01, and BAER 02 place constraints on the SUSY parameter space in the framework of minimal N=1 supergravity models with radiative breaking of the electroweak gauge symmetry.

[47] ELLIS 02 places constraints on the soft supersymmetry breaking masses in the framework of minimal N=1 supergravity models with radiative breaking of the electroweak gauge symmetry.

[48] LAHANAS 02 places constraints on the SUSY parameter space in the framework of minimal N=1 supergravity models with radiative breaking of the electroweak gauge symmetry. Focuses on the role of pseudo-scalar Higgs exchange.

[49] BARGER 01C use the cosmic relic density inferred from recent CMB measurements to constrain the parameter space in the framework of minimal N=1 supergravity models with radiative breaking of the electroweak gauge symmetry.

[50] ELLIS 01B places constraints on the SUSY parameter space in the framework of minimal N=1 supergravity models with radiative breaking of the electroweak gauge symmetry. Focuses on models with large $\tan\beta$.

[51] FENG 00 explores cosmologically allowed regions of MSSM parameter space with multi-TeV masses.

[52] LAHANAS 00 use the new cosmological data which favor a cosmological constant and its implications on the relic density to constrain the parameter space in the framework of minimal N=1 supergravity models with radiative breaking of the electroweak gauge symmetry.

[53] ELLIS 98B assumes a universal scalar mass and radiative supersymmetry breaking with universal gaugino masses. The upper limit to the LSP mass is increased due to the inclusion of $\chi - \tilde{\tau}_R$ coannihilations.

[54] EDSJO 97 included all coannihilation processes between neutralinos and charginos for any neutralino mass and composition.

[55] Notes the location of the neutralino Z resonance and h resonance annihilation corridors in minimal supergravity models with radiative electroweak breaking.

[56] BEREZINSKY 95 and ELLIS 02C places constraints on the SUSY parameter space in the framework of N=1 supergravity models with radiative breaking of the electroweak gauge symmetry but non-Universal Higgs masses.

[57] Mass of the bino (=LSP) is limited to $m_{\tilde{B}} \lesssim 350$ GeV for $m_t = 174$ GeV.

[58] DREES 93, KELLEY 93 compute the cosmic relic density of the LSP in the framework of minimal N=1 supergravity models with radiative breaking of the electroweak gauge symmetry.

[59] FALK 93 relax the upper limit to the LSP mass by considering sfermion mixing in the MSSM.

[60] MIZUTA 93 include coannihilations to compute the relic density of Higgsino dark matter.

[61] LOPEZ 92 calculate the relic LSP density in a minimal SUSY GUT model.

[62] MCDONALD 92 calculate the relic LSP density in the MSSM including exact tree-level annihilation cross sections for all two-body final states.

[63] GRIEST 91 improve relic density calculations to account for coannihilations, pole effects, and threshold effects.

[64] NOJIRI 91 uses minimal supergravity mass relations between squarks and sleptons to narrow cosmologically allowed parameter space.

[65] Mass of the bino (=LSP) is limited to $m_{\tilde{B}} \lesssim 350$ GeV for $m_t \leq 200$ GeV. Mass of the higgsino (=LSP) is limited to $m_{\tilde{H}} \lesssim 1$ TeV for $m_t \leq 200$ GeV.

[66] ROSZKOWSKI 91 calculates LSP relic density in mixed gaugino/higgsino region.

[67] Mass of the bino (=LSP) is limited to $m_{\widetilde{B}} \lesssim 550$ GeV. Mass of the higgsino (=LSP) is limited to $m_{\widetilde{H}} \lesssim 3.2$ TeV.

[68] KRAUSS 83 finds $m_{\widetilde{\gamma}}$ not 30 eV to 2.5 GeV. KRAUSS 83 takes into account the gravitino decay. Find that limits depend strongly on reheated temperature. For example a new allowed region $m_{\widetilde{\gamma}}$ = 4–20 MeV exists if $m_{\text{gravitino}}$ <40 TeV. See figure 2.

Unstable $\widetilde{\chi}_1^0$ (Lightest Neutralino) MASS LIMIT

Unless otherwise stated, results in this section assume spectra and production rates as evaluated in the MSSM. Unless otherwise stated, the goldstino or gravitino mass $m_{\widetilde{G}}$ is assumed to be negligible relative to all other masses. In the following, $\widetilde{G}$ is assumed to be undetected and to give rise to a missing energy ($\not{E}$) signature.

[69] ABDALLAH 03D use data from $\sqrt{s}$= 161-208 GeV. They look for 4-tau + $\not{E}$ final states, expected in GMSB when the $\widetilde{\tau}_1$ is the NLSP, and 4-lepton + $\not{E}$ final states, expected in the co-NLSP scenario, and assuming a short-lived $\widetilde{\chi}_1^0$ ($m(\widetilde{G})$ < 1 eV). Limits are computed in the plane ($m(\widetilde{\tau}_1)$,$m(\widetilde{\chi}_1^0)$) from a scan of the GMSB parameters space, after combining these results with the search for slepton pair production from the same paper to cover prompt decays and for the case of $\widetilde{\chi}_1^0$ NLSP from ABREU 00Z. The limit above is reached for a single generation of messengers and when the $\widetilde{\tau}_1$ is the NLSP. Stronger limits are obtained when more messenger generations are assumed or when the other sleptons are co-NLSP, see their Fig. 10. Supersedes the results of ABREU 01G.

[70] HEISTER 03C use the data from $\sqrt{s}$= 189-209 GeV to search for $\gamma\not{E}_T$ final states with non-pointing photons and $\gamma\gamma$ $\not{E}_T$ events. Interpreted in the framework of Minimal GMSB, a lower bound on the $\widetilde{\chi}_1^0$ mass is obtained as function of its lifetime. For a laboratory lifetime of less than 3 ns, the limit at 95% CL is 98.8 GeV. For other lifetimes, see their Fig. 5. These results are interpreted in a more general GMSB framework in HEISTER 02R.

[71] HEISTER 03C use the data from $\sqrt{s}$= 189-209 GeV to search for $\gamma\not{E}_T$ final states. They obtained an upper bound on the cross section for the process $e^+e^- \to \widetilde{G}\widetilde{\chi}_1^0$, followed by the prompt decay $\widetilde{\chi}_1^0 \to \gamma\widetilde{G}$, shown in their Fig. 4. These results supersede BARATE 98H.

[72] ACHARD 02 searches for the production of sparticles in the case of $\not{R}$ prompt decays with $LL\overline{E}$ or $\overline{UDD}$ couplings at $\sqrt{s}$=189–208 GeV. The search is performed for direct and indirect decays, assuming one coupling at the time to be nonzero. The MSUGRA limit results from a scan over the MSSM parameter space with the assumption of gaugino and scalar mass unification at the GUT scale, imposing simultaneously the exclusions from neutralino, chargino, sleptons, and squarks analyses. The limit holds for $\overline{UDD}$ couplings and increases to 40.2 GeV for $LL\overline{E}$ couplings. For L3 limits from $LQ\overline{D}$ couplings, see ACCIARRI 01.

[73] HEISTER 02R search for signals of GMSB in the 189–209 GeV data. For the $\widetilde{\chi}_1^0$ NLSP scenario, they looked for topologies consisting of $\gamma\gamma\not{E}$ or a single γ not pointing to the interaction vertex. For the $\widetilde{\ell}$ NLSP case, the topologies consist of $\ell\ell\not{E}$ or $4\ell\not{E}$ (from $\widetilde{\chi}_1^0\widetilde{\chi}_1^0$) production), including leptons with large impact parameters, kinks, or stable particles. Limits are derived from a scan over the GMSB parameters (see their Table 5 for the ranges). The limits are valid whichever is the NLSP. The absolute mass bound on the $\widetilde{\chi}_1^0$ for any lifetime includes indirect limits from the chargino search, and from the slepton search HEISTER 02E preformed within the MSUGRA framework. A bound for any NLSP and any lifetime of 77 GeV has also been derived by using the constraints from the neutral Higgs search in HEISTER 02. Limits on the universal SUSY mass scale Λ are also derived in the paper. Supersedes the results from BARATE 00G.

[74] ABBIENDI 01 looked for final states with $\gamma\gamma\not{E}$, $\ell\ell\not{E}$, with possibly additional activity and four leptons + $\not{E}$ to search for prompt decays of $\widetilde{\chi}_1^0$ or $\widetilde{\ell}_1$ in GMSB. They derive limits in the plane ($m_{\widetilde{\chi}_1^0}$,$m_{\widetilde{\tau}_1}$), see Fig. 6, allowing either the $\widetilde{\chi}_1^0$ or a $\widetilde{\ell}_1$ to be the NLSP. Two scenarios are considered: tanβ=2 with the 3 sleptons degenerate in mass and tanβ=20 where the $\widetilde{\tau}_1$ is lighter than the other sleptons. Data taken at $\sqrt{s}$=189 GeV.

[75] ABREU 01D searches for multi-jet events, expected in the case of prompt decays from R-parity violating $\overline{UDD}$ couplings, using data from $\sqrt{s}$=189 GeV. Combined with the search for charginos, limits are obtained in the M_2 versus μ plane and a limit on the neutralino mass is derived from a scan over the parameters m_0 and tanβ. The weakest limit for $\widetilde{\chi}_1^0$ is reached for high m_0 and tanβ=1.

[76] ACCIARRI 01 searches for multi-lepton and/or multi-jet final states from $\not{R}$ prompt decays with $LL\overline{E}$, $LQ\overline{D}$, or $\overline{UDD}$ couplings at $\sqrt{s}$=189 GeV. The search is performed for direct and indirect decays of neutralinos, charginos, and scalar leptons, with the $\widetilde{\chi}_1^0$ or a $\widetilde{\ell}$ as LSP and assuming one coupling to be nonzero at a time. Mass limits are derived using simultaneously the constraints from the neutralino, chargino, and slepton analyses; and the Z^0 width measurements from ACCIARRI 00C in a scan of the parameter space assuming MSUGRA with gaugino and scalar mass universality. Updates and supersedes the results from ACCIARRI 99I.

[77] ADAMS 01 looked for neutral particles with mass > 2.2 GeV, produced by 900 GeV protons incident on a Beryllium oxide target and decaying through weak interactions into $\mu\mu$, μe, or $\mu\pi$ final states in the decay channel of the NuTeV detector (E815) at Fermilab. The number of observed events is 3 $\mu\mu$, 0 μe, and 0 $\mu\pi$ with an expected background of 0.069 ± 0.010, 0.13 ± 0.02, and 0.14 ± 0.02, respectively. The $\mu\mu$ events are consistent with the $\not{R}$ decay of a neutralino with mass around 5 GeV. However, they share several aspects with ν-interaction backgroundes. An upper limit on the differential production cross section of neutralinos in pp interactions as function of the decay length is given in Fig. 3.

[78] ABBIENDI,G 00D obtained an upper limit on the cross section for the process $e^+e^- \to \widetilde{G}\widetilde{\chi}_1^0$ followed by the prompt decay $\widetilde{\chi}_1^0 \to \gamma\widetilde{G}$ shown in Fig. 11. Data taken at $\sqrt{s}$=189 GeV. These limits include and update the results of ABBIENDI 99F.

[79] ABBIENDI,G 00D looked for $\gamma\gamma\not{E}$ final states at $\sqrt{s}$=189 GeV. The limit is for pure bino $\widetilde{B}$ NLSP and assumes $m_{\widetilde{e}_R} = 1.35 m_{\widetilde{\chi}_1^0}$ and $m_{\widetilde{e}_L} = 2.7 m_{\widetilde{\chi}_1^0}$. See Fig. 14 for the cross-section limits as function of $m_{\widetilde{\chi}_1^0}$. These limits include and update the results of ABBIENDI 99F.

[80] ABREU 00U searches for the production of charginos and neutralinos in the case of R-parity violation with $LL\overline{E}$ couplings, using data from $\sqrt{s}$=189 GeV. They investigate topologies with multiple leptons or jets plus leptons, assuming one coupling to be nonzero at the time and giving rise to direct or indirect decays. Limits are obtained in the M_2 versus μ plane and a limit on the neutralino mass is derived from a scan over the parameters m_0 and tanβ. The weakest limit for $\widetilde{\chi}_1^0$ is reached for high m_0 and tanβ=1. Supersedes the results of ABREU 00I.

[81] ABREU 00Z looks for $\gamma\not{E}$ final states using data from $\sqrt{s}$= 183–189 GeV. Assuming the decay $\widetilde{\chi}_1^0 \to \widetilde{G}\gamma$, limits on cross section are derived, see their Fig. 7.

[82] ABREU 00Z looks for diphoton +$\not{E}$ final states using data from $\sqrt{s}$= 130–189 GeV. The limit is derived for a pure bino $\widetilde{B}$ assuming the prompt decay $\widetilde{B} \to \widetilde{G}\gamma$ and $m_{\widetilde{e}_R} \gg m_{\widetilde{e}_R} = 2m_{\widetilde{B}}$. For long-lived neutralinos, cross-section limits are displayed in their Fig. 9. These results include and update limits from ABREU 99D.

[83] ABBIENDI 99T searches for the production of neutralinos in the case of R-parity violation with $LL\overline{E}$, $LQ\overline{D}$, or $\overline{UDD}$ couplings using data from $\sqrt{s}$=183 GeV. They investigate topologies with multiple leptons, jets plus leptons, or multiple jets, assuming one coupling at the time to be non-zero and giving rise to direct or indirect decays. Mixed decays (where one particle has a direct, the other an indirect decay) are also considered for the $\overline{UDD}$ couplings. Upper limits on the cross section are derived which, combined with the constraint from the Z^0 width, allow to exclude regions in the M_2 versus μ plane for any coupling. Limits on the neutralino mass are obtained for non-zero $LL\overline{E}$ couplings $> 10^{-5}$. The limit disappears for tanβ < 1.2 and it improves to 50 GeV for tan$\beta > 20$.

[84] ABE 99I looked for chargino and neutralino production, where the lightest neutralino in their decay products further decays into $\gamma\widetilde{G}$. The limit assumes the gaugino mass unification, and holds for $1 < \tan\beta < 25$, $M_2 < 200$ GeV, and all μ. ABE 99I is an expanded version of ABE 98L.

[85] ACCIARRI 99R searches for $\gamma\not{E}$ final states using data from $\sqrt{s}$=189 GeV. From limits on cross section times branching ratio, mass limits are derived in a no-scale SUGRA model, see their Fig. 5. Supersedes the results of ACCIARRI 98V.

[86] ACCIARRI 99R searches for $\gamma\not{E}$ final states using data from $\sqrt{s}$=189 GeV. From a scan over the GMSB parameter space, a limit on the mass is derived under the assumption that the neutralino is the NLSP. Supersedes the results of ACCIARRI 98V.

[87] BARATE 99E looked for the decay of gauginos via R-violating couplings $LQ\overline{D}$. The bound is significantly reduced for smaller values of m_0. Data collected at $\sqrt{s}$=130–172 GeV.

[88] ABBOTT 98 studied the chargino and neutralino production, where the lightest neutralino in their decay products further decays into $\gamma\widetilde{G}$. The limit assumes the gaugino mass unification.

[89] ABREU 98 uses data at $\sqrt{s}$=161 and 172 GeV. Upper bounds on $\gamma\gamma\not{E}$ cross section are obtained. Similar limits on $\gamma\not{E}$ are also given, relevant for $e^+e^- \to \widetilde{\chi}_1^0\widetilde{G}$ production.

[90] BARATE 98S looked for the decay of gauginos via R-violating coupling $LL\overline{E}$. The bound improves to 25 GeV if the chargino decays into neutralino which further decays into lepton pairs. Data collected at $\sqrt{s}$=130–172 GeV.

[91] ELLIS 97 reanalyzed the LEP2 ($\sqrt{s}$=161 GeV) limits of $\sigma(\gamma\gamma + E_{\text{miss}})$< 0.2 pb to exclude $m_{\widetilde{\chi}_1^0} < 63$ GeV if $m_{\widetilde{e}_L} = m_{\widetilde{e}_R} < 150$ GeV and $\widetilde{\chi}_1^0$ decays to $\gamma\widetilde{G}$ inside detector.

[92] CABIBBO 81 consider $\widetilde{\gamma} \to \gamma$ + goldstino. Photino must be either light enough (<30 eV) to satisfy cosmology bound, or heavy enough (>0.3 MeV) to have disappeared at early universe.

$\tilde{\chi}_2^0$, $\tilde{\chi}_3^0$, $\tilde{\chi}_4^0$ (Neutralinos) MASS LIMITS

Neutralinos are unknown mixtures of photinos, z-inos, and neutral higgsinos (the supersymmetric partners of photons and of Z and Higgs bosons). The limits here apply only to $\tilde{\chi}_2^0$, $\tilde{\chi}_3^0$, and $\tilde{\chi}_4^0$. $\tilde{\chi}_1^0$ is the lightest supersymmetric particle (LSP); see $\tilde{\chi}_1^0$ Mass Limits. It is not possible to quote rigorous mass limits because they are extremely model dependent; i.e. they depend on branching ratios of various $\tilde{\chi}^0$ decay modes, on the masses of decay products ($\tilde{e}$, $\tilde{\gamma}$, $\tilde{q}$, $\tilde{g}$), and on the $\tilde{e}$ mass exchanged in $e^+e^- \to \tilde{\chi}_i^0\tilde{\chi}_j^0$. Limits arise either from direct searches, or from the MSSM constraints set on the gaugino and higgsino mass parameters M_2 and μ through searches for lighter charginos and neutralinos. Often limits are given as contour plots in the $m_{\tilde{\chi}^0} - m_{\tilde{e}}$ plane vs other parameters. When specific assumptions are made, e.g. the neutralino is a pure photino ($\tilde{\gamma}$), pure z-ino ($\tilde{Z}$), or pure neutral higgsino ($\tilde{H}^0$), the neutralinos will be labelled as such.

Limits obtained from e^+e^- collisions at energies up to 136 GeV, as well as other limits from different techniques, are now superseded and have not been included in this compilation. They can be found in the 1998 Edition (The European Physical Journal **C3** 1 (1998)) of this Review.

[93] ABBIENDI 00H used the results of direct searches in the $e^+e^- \to \tilde{\chi}_1^0\tilde{\chi}_{2,3}^0$ channels, as well as the indirect limits from $\tilde{\chi}_1^0$ and $\tilde{\chi}_1^\pm$ searches, in the framework of the MSSM with gaugino and sfermion mass unification at the GUT scale. See the footnote to ABBIENDI 00H in the chargino Section for further details on the assumptions. Data collected at $\sqrt{s}$=189 GeV. The limits improve to 86.2 GeV ($\tilde{\chi}_2^0$) and 124 GeV ($\tilde{\chi}_3^0$) for tanβ=35. See their Table 6 for more details on the tanβ and m_0 dependence of the limits. Quoted values consistent with erratum published in ABBIENDI 00Y. Updates ABBIENDI 99G.

[94] ABREU 00W combines data collected at $\sqrt{s}$=189 GeV with results from lower energies. The mass limit is obtained by constraining the MSSM parameter space with gaugino and sfermion mass universality at the GUT scale, using the results of negative direct searches for neutralinos (including cascade decays and $\tilde{\tau}\,\tau$ final states) from ABREU 01, for charginos from ABREU 00J and ABREU 00T (for all Δm_+), and for charged sleptons from ABREU 01B. The results hold for the full parameter space defined by all values of M_2 and $|\mu| \leq 2$ TeV with the $\tilde{\chi}_1^0$ as LSP.

[95] ACHARD 02 searches for the production of sparticles in the case of $\not{R}$ prompt decays with $LL\overline{E}$ or $\overline{UDD}$ couplings at $\sqrt{s}$=189–208 GeV. The search is performed for direct and indirect decays, assuming one coupling at the time to be nonzero. The MSUGRA limit results from a scan over the MSSM parameter space with the assumption of gaugino and scalar mass unification at the GUT scale, imposing simultaneously the exclusions from neutralino, chargino, sleptons, and squarks analyses. The limit of $\tilde{\chi}_2^0$ holds for $\overline{UDD}$ couplings and increases to 84.0 GeV for $LL\overline{E}$ couplings. The same $\tilde{\chi}_3^0$ limit holds for both $LL\overline{E}$ and $\overline{UDD}$ couplings. For L3 limits from $LQ\overline{D}$ couplings, see ACCIARRI 01.

[96] ABREU 01B used data from $\sqrt{s}$=189 GeV to search for the production of $\tilde{\chi}_i^0\tilde{\chi}_j^0$. They looked for di-jet and di-lepton pairs with $\not{E}$ for events from $\tilde{\chi}_i^0\tilde{\chi}_j^0$ with the decay $\tilde{\chi}_j^0 \to f\overline{f}\tilde{\chi}_1^0$; multi-jet and multi-lepton pairs with or without additional photons to cover the cascade decays $\tilde{\chi}_j^0 \to f\overline{f}\tilde{\chi}_2^0$, followed by $\tilde{\chi}_j^0 \to f\overline{f}\tilde{\chi}_1^0$ or $\tilde{\chi}_j^0 \to \gamma\tilde{\chi}_1^0$; multi-tau final states from $\tilde{\chi}_2^0 \to \tilde{\tau}\,\tau$ with $\tilde{\tau} \to \tau\tilde{\chi}_1^0$. See Figs. 9 and 10 for limits on the (μ, M_2) plane for tanβ=1.0 and different values of m_0.

[97] ACCIARRI 01 searches for multi-lepton and/or multi-jet final states from $\not{R}$ prompt decays with $LL\overline{E}$, $LQ\overline{D}$, or $\overline{UDD}$ couplings at $\sqrt{s}$=189 GeV. The search is performed for direct and indirect decays of neutralinos, charginos, and scalar leptons, with the $\tilde{\chi}_1^0$ or a $\tilde{\ell}$ as LSP and assuming one coupling to be nonzero at a time. Mass limits are derived using simultaneously the constraints from the neutralino, chargino, and slepton analyses; and the Z^0 width measurements from ACCIARRI 00C in a scan of the parameter space assuming MSUGRA with gaugino and scalar mass universality. Updates and supersedes the results from ACCIARRI 99I.

[98] ABREU 00U searches for the production of charginos and neutralinos in the case of R-parity violation with $LL\overline{E}$ couplings, using data from $\sqrt{s}$=189 GeV. They investigate topologies with multiple leptons or jets plus leptons, assuming one coupling to be nonzero at the time and giving rise to direct or indirect decays. Limits are obtained in the M_2 versus μ plane and a limit on the neutralino mass is derived from a scan over the parameters m_0 and tanβ.

[99] ABREU 00Z looks for diphoton + $\not{E}$ final states using data from $\sqrt{s}$= 130–189 GeV. They obtain an upper bound on the cross section, see their Fig. 10 for limits in the $(m_{\tilde{\chi}_2^0}, m_{\tilde{\chi}_1^0})$ plane. Updates ABREU 99D.

[100] ABBIENDI 99F looked for $\gamma\not{E}$ final states at $\sqrt{s}$=183 GeV. They obtained an upper bound on the cross section for the production $e^+e^- \to \tilde{\chi}_2^0\tilde{\chi}_1^0$ followed by the prompt decay $\tilde{\chi}_2^0 \to \gamma\tilde{\chi}_1^0$ of 0.075–0.80 pb in the region $m_{\tilde{\chi}_2^0} + m_{\tilde{\chi}_1^0} > m_{Z^0}$, $m_{\tilde{\chi}_2^0}$=91–183 GeV, and $\Delta m_0 > 5$ GeV. See Fig. 7 for explicit limits in the $(m_{\tilde{\chi}_2^0}, m_{\tilde{\chi}_1^0})$ plane.

[101] ABBIENDI 99F looked for $\gamma\gamma\not{E}$ final states at $\sqrt{s}$=183 GeV. They obtained an upper bound on the cross section for the production $e^+e^- \to \tilde{\chi}_2^0\tilde{\chi}_2^0$ followed by the prompt decay $\tilde{\chi}_2^0 \to \gamma\tilde{\chi}_1^0$ of 0.08–0.37 pb for $m_{\tilde{\chi}_2^0}$=45–81.5 GeV, and $\Delta m_0 > 5$ GeV. See Fig. 11 for explicit limits in the $(m_{\tilde{\chi}_2^0}, m_{\tilde{\chi}_1^0})$ plane.

[102] ACCIARRI 99R searches for $\gamma\not{E}$ and $\gamma\gamma\not{E}$ final states using data from $\sqrt{s}$=189 GeV. Limits on the cross section for the processes $e^+e^- \to \tilde{\chi}_2^0\tilde{\chi}_{2,1}^0$ with the decay $\tilde{\chi}_2^0 \to \tilde{\chi}_1^0\gamma$ are derived, as shown in their Figs. 4 and 7. Supersedes the results of ACCIARRI 98V.

[103] ABBOTT 98C searches for trilepton final states (ℓ=e,μ). See footnote to ABBOTT 98C in the Chargino Section for details on the assumptions. Assuming a negligible decay rate of $\tilde{\chi}_1^\pm$ and $\tilde{\chi}_2^0$ to quarks, they obtain $m_{\tilde{\chi}_2^0} \gtrsim 103$ GeV.

[104] ABE 98J searches for trilepton final states (ℓ=e,μ). See footnote to ABE 98J in the Chargino Section for details on the assumptions. The quoted result for $m_{\tilde{\chi}_2^0}$ corresponds to the best limit within the selected range of parameters, obtained for $m_{\tilde{q}} > m_{\tilde{g}}$, tan$\beta$=2, and μ=− 600 GeV.

[105] ACCIARRI 98F is obtained from direct searches in the $e^+e^- \to \tilde{\chi}_{1,2}^0\tilde{\chi}_2^0$ production channels, and indirectly from $\tilde{\chi}_1^\pm$ and $\tilde{\chi}_1^0$ searches within the MSSM. See footnote to ACCIARRI 98F in the chargino Section for further details on the assumptions. Data taken at $\sqrt{s}$ = 130–172 GeV.

[106] ACCIARRI 98V looked for $\gamma(\gamma)\not{E}$ final states at $\sqrt{s}$=183 GeV. They obtained an upper bound on the cross section for the production $e^+e^- \to \tilde{\chi}_2^0\tilde{\chi}_{1,2}^0$ followed by the prompt decay $\tilde{\chi}_2^0 \to \gamma\tilde{\chi}_1^0$. See Figs. 4a and 6a for explicit limits in the $(m_{\tilde{\chi}_2^0}, m_{\tilde{\chi}_1^0})$ plane.

[107] BARATE 98H looked for $\gamma\gamma$ $\not{E}$ final states at $\sqrt{s}$ = 161,172 GeV. They obtained an upper bound on the cross section for the production $e^+e^- \to \tilde{\chi}_2^0\tilde{\chi}_2^0$ followed by the prompt decay $\tilde{\chi}_2^0 \to \gamma\tilde{\chi}_1^0$ of 0.4–0.8 pb for $m_{\tilde{\chi}_2^0}$ = 10–80 GeV. The bound above is for the specific case of $\tilde{\chi}_1^0 = \tilde{H}^0$ and $\tilde{\chi}_2^0 = \tilde{\gamma}$ and $m_{\tilde{e}_R}$ = 100 GeV. See Fig. 6 and 7 for explicit limits in the $(\tilde{\chi}_2^0, \tilde{\chi}_1^0)$ plane and in the $(\tilde{\chi}_2^0, \tilde{e}_R)$ plane.

[108] BARATE 98J looked for $\gamma\gamma$ $\not{E}$ final states at $\sqrt{s}$ = 161–183 GeV. They obtained an upper bound on the cross section for the production $e^+e^- \to \tilde{\chi}_2^0\tilde{\chi}_2^0$ followed by the prompt decay $\tilde{\chi}_2^0 \to \gamma\tilde{\chi}_1^0$ of 0.08–0.24 pb for $m_{\tilde{\chi}_2^0} < 91$ GeV. The bound above is for the specific case of $\tilde{\chi}_1^0 = \tilde{H}^0$ and $\tilde{\chi}_2^0 = \tilde{\gamma}$ and $m_{\tilde{e}_R}$ = 100 GeV.

[109] ABACHI 96 searches for 3-lepton final states. Efficiencies are calculated using mass relations and branching ratios in the Minimal Supergravity scenario. Results are presented as lower bounds on $\sigma(\tilde{\chi}_1^\pm\tilde{\chi}_2^0) \times$ B($\tilde{\chi}_1^\pm \to \ell\nu_\ell\tilde{\chi}_1^0$) × B($\tilde{\chi}_2^0 \to \ell^+\ell^-\tilde{\chi}_1^0$) as a function of $m_{\tilde{\chi}_1^0}$. Limits range from 3.1 pb ($m_{\tilde{\chi}_1^0}$ = 45 GeV) to 0.6 pb ($m_{\tilde{\chi}_1^0}$ = 100 GeV).

[110] ABE 96K looked for trilepton events from chargino-neutralino production. They obtained lower bounds on $m_{\tilde{\chi}_2^0}$ as a function of μ. The lower bounds are in the 45–50 GeV range for gaugino-dominant $\tilde{\chi}_2^0$ with negative μ, if tanβ <10. See paper for more details of the assumptions.

$\tilde{\chi}_1^\pm$, $\tilde{\chi}_2^\pm$ (Charginos) MASS LIMITS

Charginos are unknown mixtures of w-inos and charged higgsinos (the supersymmetric partners of W and Higgs bosons). A lower mass limit for the lightest chargino ($\tilde{\chi}_1^\pm$) of approximately 45 GeV, independent of the field composition and of the decay mode, has been obtained by the LEP experiments from the analysis of the Z width and decays. These results, as well as other now superseded limits from e^+e^- collisions at energies below 136 GeV, and from hadronic collisions, can be found in the 1998 Edition (The European Physical Journal **C3** 1 (1998)) of this Review.

Unless otherwise stated, results in this section assume spectra, production rates, decay modes and branching ratios as evaluated in the MSSM, with gaugino and sfermion mass unification at the GUT scale. These papers generally study production of $\tilde{\chi}_1^0\tilde{\chi}_2^0$, $\tilde{\chi}_1^+\tilde{\chi}_1^-$ and (in the case of hadronic collisions) $\tilde{\chi}_1^+\tilde{\chi}_2^0$ pairs, including the effects of cascade decays. The mass limits on $\tilde{\chi}_1^\pm$ are either direct, or follow indirectly from the constraints set by the non-observation of $\tilde{\chi}_2^0$ states on the gaugino and higgsino MSSM parameters M_2 and μ. For generic values of the MSSM parameters, limits from high-energy e^+e^- collisions coincide with the highest value of the mass allowed by phase-space, namely $m_{\tilde{\chi}_1^\pm} \lesssim \sqrt{s}/2$. At the time of this writing, preliminary and

unpublished results from the 2000 run of LEP2 at $\sqrt{s}$ up to $\simeq$ 209 GeV give therefore a lower mass limit of approximately 104 GeV valid for general MSSM models. The limits become however weaker in special regions of the MSSM parameter space where the detection efficiencies or production cross sections are suppressed. For example, this may happen when: (i) the mass differences $\Delta m_+ = m_{\widetilde{\chi}_1^\pm} - m_{\widetilde{\chi}_1^0}$ or $\Delta m_\nu = m_{\widetilde{\chi}_1^\pm} - m_{\widetilde{\nu}}$ are very small, and the detection efficiency is reduced; (ii) the electron sneutrino mass is small, and the $\widetilde{\chi}_1^\pm$ production rate is suppressed due to a destructive interference between s and t channel exchange diagrams. The regions of MSSM parameter space where the following limits are valid are indicated in the comment lines or in the footnotes.

[111] ABBIENDI 03H used e^+e^- data at $\sqrt{s}$ = 188-209 GeV to search for chargino pair production in the case of small Δm_+. They select events with an energetic photon, large $\not{E}$ and little hadronic or leptonic activity. The bound applies to higgsino-like charginos with zero lifetime and a 100% branching ratio $\widetilde{\chi}_1^\pm \to \widetilde{\chi}_1^0 W^*$. The mass limit for gaugino-like charginos, in case of non-universal gaugino masses, is of 92 GeV for $m_{\widetilde{\nu}} = 1000$ GeV and is lowered to 74 GeV for $m_{\widetilde{\nu}} \geq 100$ GeV. Limits in the plane $(m_{\widetilde{\chi}_1^\pm}, \Delta m_+)$ are shown in Fig. 7. Exclusion regions are also derived for the AMSB scenario in the $(m_{3/2}, \tan\beta)$ plane, see their Fig. 9.

[112] ABDALLAH 03M searches for the production of charginos using data from $\sqrt{s}$= 192 to 208 GeV to investigate topologies with multiple leptons, jets plus leptons, multi-jets, or isolated photons. The first limit holds for tan$\beta \geq 1$ and is obtained at $\Delta m_+ = 3$ GeV in the higgsino region. For $\Delta m_+ \geq 10$ (5) GeV and large m_0, the limit improves to 102.7 (101.7) GeV. For the region of small Δm_+, all data from $\sqrt{s}$= 130 to 208 GeV are used to investigate final states with heavy stable charged particles, decay vertices inside the detector and soft topologies with a photon from initial state radiation. The second limit is obtained in the higgsino region, assuming gaugino mass universality at the GUT scale and $1 < \tan\beta < 50$. For the case of non-universality of gaugino masses, the parameter space is scanned in the domain $1 < \tan\beta < 50$ and, for $\Delta m_+ < 3$ GeV, for values of M_1, M_2 and μ such that $M_2 \leq 2M_1 \leq 10M_2$ and $|\mu| \geq M_2$. The third limit is obtained in the gaugino region. See Fig. 36 for the dependence of the low Δm_+ limits on Δm_+. These limits include and update the results of ABREU 00J and ABREU 00T.

[113] ABDALLAH 03M uses data from $\sqrt{s}$ = 192–208 GeV to obtain limits in the framework of the MSSM with gaugino and sfermion mass universality at the GUT scale. An indirect limit on the mass of charginos is derived by constraining the MSSM parameter space by the results from direct searches for neutralinos (including cascade decays), for charginos and for sleptons. These limits are valid for values of $M_2 < 1$ TeV, $|\mu| \leq 2$ TeV with the $\widetilde{\chi}_1^0$ as LSP. Constraints from the Higgs search in the M_h^{max} scenario assuming m_t=174.3 GeV are included. The quoted limit applies if there is no mixing in the third family or when $m_{\widetilde{\tau}_1} - m_{\widetilde{\chi}_1^0} > 6$ GeV. If mixing is included the limit degrades to 90 GeV. See Fig. 43 for the mass limits as a function of tanβ. These limits update the results of ABREU 00W.

[114] HEISTER 02J search for chargino production with small Δm_+ in final states with a hard isolated initial state radiation photon and few low-momentum particles, using 189–208 GeV data. This search is sensitive in the intermediate Δm_+ region. Combined with searches for $\not{E}$ topologies and for stable charged particles, the above bound is obtained for m_0 larger than few hundred GeV, $1 < \tan\beta < 300$ and holds for any chargino field contents. For light scalars, the general limit reduces to the one from the Z^0, but under the assumption of gaugino and sfermion mass unification the above bound is recovered. See Figs. 4–6 for the more general dependence of the limits on Δm_+. Updates BARATE 98X.

[115] ABBIENDI 00H data collected at $\sqrt{s}$=189 GeV. The results hold over the full parameter space defined by $0 \leq M_2 \leq 2$ TeV, $|\mu| \leq 500$ GeV, $m_0 \leq 500$ GeV, A=$\pm M_2$, $\pm m_0$, and 0. The results of slepton searches from ABBIENDI 00G were used to help set constraints in the region of small m_0. The limit improves to 78 GeV for tanβ=1.5. See their Table 5 and Fig. 4 for the tanβ and M_2 dependence of the limits. Updates ABBIENDI 99G.

[116] ACCIARRI 00D data collected at $\sqrt{s}$=189 GeV. The results hold over the full parameter space defined by $0.7 \leq \tan\beta \leq 60$, $0 \leq M_2 \leq 2$ TeV, $|\mu| \leq 2$ TeV $m_0 \leq 500$ GeV. The results of slepton searches from ACCIARRI 99W are used to help set constraints in the region of small m_0. See their Figs. 5 for the tanβ and M_2 dependence on the limits. See the text for the impact of a large B($\widetilde{\chi}^\pm \to \tau\widetilde{\nu}_\tau$) on the result. The region of small Δm_+ is excluded by the analysis of ACCIARRI 00K. Updates ACCIARRI 98F.

[117] ACCIARRI 00K searches for the production of charginos with small Δm_+ using data from $\sqrt{s}$=189 GeV. They investigate soft final states with a photon from initial state radiation. The results are combined with the limits on prompt decays from ACCIARRI 00D and from heavy stable charged particles from ACCIARRI 99L (see Heavy Charged Lepton Searches). The production and decay branching ratios are evaluated within the MSSM, assuming heavy sfermions. The parameter space is scanned in the domain $1 < \tan\beta < 50$, $0.3 < M_1/M_2 < 50$, and $0 < |\mu| < 2$ TeV. The limit is obtained in the higgsino region and improves to 78.6 GeV for gaugino-like charginos. The limit is unchanged for light scalar quarks. For light $\widetilde{\tau}$ or $\widetilde{\nu}_\tau$, the limit is unchanged in the gaugino-like region and is lowered by 0.8 GeV in the higgsino-like case. For light $\widetilde{\mu}$ or $\widetilde{\nu}_\mu$, the limit is unchanged in the higgsino-like region and is lowered by 0.9 GeV in the gaugino-like region. No direct mass limits are obtained for light $\widetilde{e}$ or $\widetilde{\nu}_e$.

[118] ABDALLAH 03D use data from $\sqrt{s}$= 183-208 GeV. They look for final states with two acoplanar leptons, expected in GMSB when the $\widetilde{\tau}_1$ is the NLSP and assuming a short-lived $\widetilde{\chi}_1^\pm$. Limits are obtained in the plane (m($\widetilde{\tau}$),m($\widetilde{\chi}_1^\pm$)) for different domains of m($\widetilde{G}$), after combining these results with the search for slepton pair production from the same paper. The limit above is valid if the $\widetilde{\tau}_1$ is the NLSP for all values of m($\widetilde{G}$) provided $m(\widetilde{\chi}_1^\pm) - m(\widetilde{\tau}_1) \geq 0.3$ GeV. For larger m($\widetilde{G}$) > 100 eV the limit improves to 102 GeV, see their Fig. 11. In the co-NLSP scenario, the limits are 96 and 102 GeV for all m($\widetilde{G}$) and m($\widetilde{G}$) > 100 eV, respectively. Supersedes the results of ABREU 01G.

[119] HEISTER 03G searches for the production of charginos prompt decays. in the case of $R\!\!\!/$ prompt decays with $LL\overline{E}$, $LQ\overline{D}$ or $\overline{UDD}$ couplings at $\sqrt{s}$=189–209 GeV. The search is performed for indirect decays, assuming one coupling at a time to be non-zero. The limit holds for tanβ = 1.41. Excluded regions in the (μ, M_2) plane are shown in their Fig. 3.

[120] ACHARD 02 searches for the production of sparticles in the case of $R\!\!\!/$ prompt decays with $LL\overline{E}$ or $\overline{UDD}$ couplings at $\sqrt{s}$=189–208 GeV. The search is performed for direct and indirect decays, assuming one coupling at the time to be nonzero. The MSUGRA limit results from a scan over the MSSM parameter space with the assumption of gaugino and scalar mass unification at the GUT scale, imposing simultaneously the exclusions from neutralino, chargino, sleptons, and squarks analyses. The limit of $\widetilde{\chi}_1^\pm$ holds for $\overline{UDD}$ couplings and increases to 103.0 GeV for $LL\overline{E}$ couplings. For L3 limits from $LQ\overline{D}$ couplings, see ACCIARRI 01.

[121] GHODBANE 02 reanalyzes DELPHI data at $\sqrt{s}$=189 GeV in the presence of complex phases for the MSSM parameters.

[122] ABREU 01C looked for τ pairs with $\not{E}$ at $\sqrt{s}$=183–189 GeV to search for the associated production of charginos, followed by the decay $\widetilde{\chi}^\pm \to \tau J$, J being an invisible massless particle. See Fig. 6 for the regions excluded in the (μ,M_2) plane.

[123] ABREU 01D searches for multi-jet events, expected in the case of prompt decays from R-parity violating $\overline{UDD}$ couplings, using data from $\sqrt{s}$=189 GeV. They investigate topologies with 6 or 10 jets, originating from direct or indirect decays. Limits are obtained in the M_2 versus μ plane and a limit on the chargino mass is derived from a scan over the parameters m_0 and tanβ.

[124] ACCIARRI 01 searches for multi-lepton and/or multi-jet final states from $R\!\!\!/$ prompt decays with $LL\overline{E}$, $LQ\overline{D}$, or $\overline{UDD}$ couplings at $\sqrt{s}$=189 GeV. The search is performed for direct and indirect decays of neutralinos, charginos, and scalar leptons, with the $\widetilde{\chi}_1^0$ or a $\widetilde{\ell}$ as LSP and assuming one coupling to be nonzero at a time. Mass limits are derived using simultaneously the constraints from the neutralino, chargino, and slepton analyses; and the Z^0 width measurements from ACCIARRI 00C in a scan of the parameter space assuming MSUGRA with gaugino and scalar mass universality. Updates and supersedes the results from ACCIARRI 99I.

[125] BARATE 01B searches for the production of charginos in the case of $R\!\!\!/$ prompt decays with $LL\overline{E}$, $LQ\overline{D}$, or $\overline{UDD}$ couplings at $\sqrt{s}$=189–202 GeV. The search is performed for indirect decays, assuming one coupling at a time to be nonzero. Updates BARATE 00H.

[126] ABREU 00U searches for the production of charginos and neutralinos in the case of R-parity violation with $LL\overline{E}$ couplings, using data from $\sqrt{s}$=189 GeV. They investigate topologies with multiple leptons or jets plus leptons, assuming one coupling to be nonzero at the time and giving rise to direct or indirect decays. Limits are obtained in the M_2 versus μ plane and a limit on the neutralino mass is derived from a scan over the parameters m_0 and tanβ. Supersedes the results of ABREU 00I.

[127] ABREU 00V use data from $\sqrt{s}$= 183–189 GeV. They look for final states with two acoplanar leptons, expected in GMSB when the $\widetilde{\tau}_1$ is the NLSP and assuming a short-lived $\widetilde{\chi}_1^\pm$. Limits are obtained in the plane $(m_{\widetilde{\tau}}, m_{\widetilde{\chi}_1^\pm})$ for different domains of $m_{\widetilde{G}}$, after combining these results with the search for slepton pair production in the SUGRA framework from ABREU 01 to cover prompt decays and on stable particle searches from ABREU 00Q. The limit above is valid for all values of $m_{\widetilde{G}}$.

[128] CHO 00B studied constraints on the MSSM spectrum from precision EW observables. Global fits favour charginos with masses at the lower bounds allowed by direct searches. Allowing for variations of the squark and slepton masses does not improve the fits.

[129] ABBIENDI 99T searches for the production of neutralinos in the case of R-parity violation with $LL\overline{E}$, $LQ\overline{D}$, or $\overline{UDD}$ couplings using data from $\sqrt{s}$=183 GeV. They investigate

topologies with multiple leptons, jets plus leptons, or multiple jets, assuming one coupling at the time to be non-zero and giving rise to direct or indirect decays. Mixed decays (where one particle has a direct, the other an indirect decay) are also considered for the $\overline{UDD}$ couplings. Upper limits on the cross section are derived which, combined with the constraint from the Z^0 width, allow to exclude regions in the M_2 versus μ plane for any coupling. Limits on the chargino mass are obtained for non-zero $LL\overline{E}$ couplings $> 10^{-5}$ and assuming decays via a W^*.

130 ABE 99I looked for chargino and neutralino production, where the lightest neutralino in their decay products further decays into $\gamma\,\widetilde{G}$. The limit assumes the gaugino mass unification, and holds for $1 < \tan\beta < 25$, $M_2 < 200$ GeV, and all μ. ABE 99I is an expanded version of ABE 98L.

131 MALTONI 99B studied the effect of light chargino-neutralino to the electroweak precision data with a particular focus on the case where they are nearly degenerate ($\Delta m_{\pm} \sim 1$ GeV) which is difficult to exclude from direct collider searches. The quoted limit is for higgsino-like case while the bound improves to 56 GeV for wino-like case. The values of the limits presented here are obtained in an update to MALTONI 99B, as described in MALTONI 00.

132 ABBOTT 98 studied the chargino and neutralino production, where the lightest neutralino in their decay products further decays into $\gamma\,\widetilde{G}$. The limit assumes the gaugino mass unification.

133 ABBOTT 98C searches for trilepton final states (ℓ=e,μ). Efficiencies are calculated using mass relations in the Minimal Supergravity scenario, exploring the domain of parameter space defined by $m_{\widetilde{\chi}_1^\pm}=m_{\widetilde{\chi}_2^0}$ and $m_{\widetilde{\chi}_1^\pm}=2m_{\widetilde{\chi}_1^0}$. Results are presented in Fig. 1 as upper bounds on $\sigma(p\overline{p} \to \widetilde{\chi}_1^\pm\widetilde{\chi}_2^0)\times B(3\ell)$. Assuming equal branching ratio for all possible leptonic decays, limits range from 2.6 pb ($m_{\widetilde{\chi}_1^\pm}$=45 GeV) to 0.4 pb ($m_{\widetilde{\chi}_1^\pm}$=124 GeV) at 95%CL. Assuming a negligible decay rate of $\widetilde{\chi}_1^\pm$ and $\widetilde{\chi}_2^0$ to quarks, this corresponds to $m_{\widetilde{\chi}_1^\pm} > 103$ GeV.

134 ABE 98J searches for trilepton final states (ℓ=e,μ). Efficiencies are calculated using mass relations in the Minimal Supergravity scenario, exploring the domain of parameter space defined by $1.1 < \tan\beta < 8$, $-1000 < \mu(\text{GeV}) < -200$, and $m_{\widetilde{q}}/m_{\widetilde{g}}$=1–2. In this region $m_{\widetilde{\chi}_1^\pm} \sim m_{\widetilde{\chi}_2^0}$ and $m_{\widetilde{\chi}_1^\pm} \sim 2m_{\widetilde{\chi}_1^0}$. Results are presented in Fig. 1 as upper bounds on $\sigma(p\overline{p} \to \widetilde{\chi}_1^\pm\widetilde{\chi}_2^0)\times B(3\ell)$. Limits range from 0.8 pb ($m_{\widetilde{\chi}_1^\pm}$=50 GeV) to 0.23 pb ($m_{\widetilde{\chi}_1^\pm}$=100 GeV) at 95%CL. The gaugino mass unification hypothesis and the assumed mass relation between squarks and gluinos define the value of the leptonic branching ratios. The quoted result corresponds to the best limit within the selected range of parameters, obtained for $m_{\widetilde{q}} > m_{\widetilde{g}}$, $\tan\beta$=2, and μ=−600 GeV. Mass limits for different values of $\tan\beta$ and μ are given in Fig. 2.

135 ACKERSTAFF 98K looked for dilepton+$\not{E}_T$ final states at $\sqrt{s}$=130–172 GeV. Limits on $\sigma(e^+e^- \to \widetilde{\chi}_1^+\widetilde{\chi}_1^-)\times B^2(\ell)$, with $B(\ell)=B(\chi^+ \to \ell^+\nu_\ell\chi_1^0)$ ($B(\ell)=B(\chi^+ \to \ell^+\overline{\nu}_\ell)$), are given in Fig. 16 (Fig. 17).

136 ACKERSTAFF 98L limit is obtained for $0 < M_2 < 1500$, $|\mu| < 500$ and $\tan\beta > 1$, but remains valid outside this domain. The dependence on the trilinear-coupling parameter A is studied, and found negligible. The limit holds for the smallest value of m_0 consistent with scalar lepton constraints (ACKERSTAFF 97H) and for all values of m_0 where the condition $\Delta m_{\widetilde{\nu}} > 2.0$ GeV is satisfied. $\Delta m_{\widetilde{\nu}} > 10$ GeV if $\widetilde{\chi}^\pm \to \ell\,\widetilde{\nu}_\ell$. The limit improves to 84.5 GeV for m_0=1 TeV. Data taken at $\sqrt{s}$=130–172 GeV.

137 ACKERSTAFF 98V excludes the light gluino with universal gaugino mass where charginos, neutralinos decay as $\widetilde{\chi}_1^\pm, \widetilde{\chi}_2^0 \to q\overline{q}\,\widetilde{g}$ from total hadronic cross sections at $\sqrt{s}$=130–172 GeV. See paper for the case of nonuniversal gaugino mass.

138 CARENA 97 studied the constraints on chargino and sneutrino masses from muon $g-2$. The bound can be important for large $\tan\beta$.

139 KALINOWSKI 97 studies the constraints on the chargino-neutralino parameter space from limits on $\Gamma(W \to \widetilde{\chi}_1^\pm\widetilde{\chi}_1^0)$ achievable at LEP2. This is relevant when $\widetilde{\chi}_1^\pm$ is "invisible," i.e., if $\widetilde{\chi}_1^\pm$ dominantly decays into $\widetilde{\nu}_\ell\ell^\pm$ with little energy for the lepton. Small otherwise allowed regions could be excluded.

140 ABE 96K looked for trilepton events from chargino-neutralino production. The bound on $m_{\widetilde{\chi}_1^\pm}$ can reach up to 47 GeV for specific choices of parameters. The limits on the combined production cross section times 3-lepton branching ratios range between 1.4 and 0.4 pb, for $45 < m_{\widetilde{\chi}_1^\pm}(\text{GeV}) < 100$. See the paper for more details on the parameter dependence of the results.

Long-lived $\widetilde{\chi}^\pm$ (Chargino) MASS LIMITS

Limits on charginos which leave the detector before decaying.

VALUE (GeV)	CL%		DOCUMENT ID		TECN	COMMENT

141 ABBIENDI 03L used e^+e^- data at $\sqrt{s}$ = 130-209 GeV to select events with two high momentum tracks with anomalous dE/dx. The excluded cross section is compared to the theoretical expectation as a function of the heavy particle mass in their Fig. 3. The bounds are valid for colorless fermions with lifetime longer than 10^{-6} s. Supersedes the results from ACKERSTAFF 98P.

142 ABREU 00T searches for the production of heavy stable charged particles, identified by their ionization or Cherenkov radiation, using data from $\sqrt{s}$= 130 to 189 GeV. These limits include and update the results of ABREU 98P.

143 BARATE 97K uses e^+e^- data collected at $\sqrt{s}$ = 130–172 GeV. Limit valid for $\tan\beta = \sqrt{2}$ and $m_{\widetilde{\nu}} > 100$ GeV. The limit improves to 86 GeV for $m_{\widetilde{\nu}} > 250$ GeV.

$\widetilde{\nu}$ (Sneutrino) MASS LIMIT

The limits may depend on the number, $N(\widetilde{\nu})$, of sneutrinos assumed to be degenerate in mass. Only $\widetilde{\nu}_L$ (not $\widetilde{\nu}_R$) is assumed to exist. It is possible that $\widetilde{\nu}$ could be the lightest supersymmetric particle (LSP).

We report here, but do not include in the Listings, the limits obtained from the final, but unpublished, fit of the final results obtained by the LEP Collaborations on the invisible width of the Z boson ($\Delta\Gamma_{\text{inv.}} < 2.0$ MeV, LEP 03): $m_{\widetilde{\nu}} > 43.7$ GeV ($N(\widetilde{\nu})$=1) and $m_{\widetilde{\nu}} > 44.7$ GeV ($N(\widetilde{\nu})$=3) .

144 ABDALLAH 03M uses data from $\sqrt{s}$ = 192–208 GeV to obtain limits in the framework of the MSSM with gaugino and sfermion mass universality at the GUT scale. An indirect limit on the mass is derived by constraining the MSSM parameter space by the results from direct searches for neutralinos (including cascade decays) and for sleptons. These limits are valid for values of $M_2 < 1$ TeV, $|\mu| \leq 1$ TeV with the $\widetilde{\chi}_1^0$ as LSP. The quoted limit is obtained when there is no mixing in the third family. See Fig. 43 for the mass limits as a function of $\tan\beta$. These limits update the results of ABREU 00W.

145 HEISTER 02N derives a bound on $m_{\widetilde{\nu}_e}$ by exploiting the mass relation between the $\widetilde{\nu}_e$ and $\widetilde{e}$, based on the assumption of universal GUT scale gaugino and scalar masses $m_{1/2}$ and m_0 and the search described in the $\widetilde{e}$ section. In the MSUGRA framework with radiative electroweak symmetry breaking, the limit improves to $m_{\widetilde{\nu}_e} > 130$ GeV, assuming a trilinear coupling A_0=0 at the GUT scale. See Figs. 5 and 7 for the dependence of the limits on $\tan\beta$.

146 ADRIANI 93M limit from $\Delta\Gamma(Z)$(invisible)< 16.2 MeV.

147 DECAMP 92 limit is from Γ(invisible)/$\Gamma(\ell\ell) = 5.91 \pm 0.15$ ($N_\nu = 2.97 \pm 0.07$).

148 ALEXANDER 91F limit is for one species of $\widetilde{\nu}$ and is derived from Γ(invisible, new)/$\Gamma(\ell\ell)$ < 0.38.

149 ABDALLAH 03F looked for events of the type $e^+e^- \to \widetilde{\nu} \to \widetilde{\chi}^0\nu$, $\widetilde{\chi}^\pm\ell^\mp$ followed by $\not{R}$ decays of the $\widetilde{\chi}^0$ via λ_{1j1} (j = 2,3) couplings in the data at $\sqrt{s}$= 183-208 GeV. From a scan over the SUGRA parameters, they derive upper limits on the λ_{1j1} couplings as a function of the sneutrino mass, see their Figs. 5-8.

150 ACOSTA 03E search for $e\mu$, $e\tau$ and $\mu\tau$ final states, and sets limits on the product of production cross-section and decay branching ratio for a $\widetilde{\nu}$ in RPV models (see Fig. 3).

151 HEISTER 03G searches for the production of sneutrinos in the case of $\not{R}$ prompt decays with $LL\overline{E}$, $LQ\overline{D}$ or $\overline{UDD}$ couplings at $\sqrt{s}$=189–209 GeV. The search is performed for direct and indirect decays, assuming one coupling at a time to be non-zero. The limit holds for indirect $\overline{\nu}$ decays via $\overline{UDD}$ couplings and $\Delta m > 10$ GeV. Stronger limits are reached for ($\overline{\nu}_e$,$\overline{\nu}_{\mu,\tau}$) for $LL\overline{E}$ direct (100,90) GeV or indirect (98,89) GeV and for $LQ\overline{D}$ direct (−,79) GeV or indirect (91,78) GeV couplings. For $LL\overline{E}$ indirect decays, use is made of the bound $m(\widetilde{\chi}_1^0) > 23$ GeV from BARATE 98S. Supersedes the results from BARATE 01B.

152 ABAZOV 02H looked in 94 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV for events with at least 2 muons and 2 jets for s-channel production of $\widetilde{\mu}$ or $\widetilde{\nu}$ and subsequent decay via $\not{R}$ couplings $LQ\overline{D}$. A scan over the MSUGRA parameters is performed to exclude regions of the $(m_0, m_{1/2})$ plane, examples being shown in Fig. 2.

[153] ACHARD 02 searches for the associated production of sneutrinos in the case of $R\!\!\!/$ prompt decays with $LL\overline{E}$ or $\overline{UDD}$ couplings at $\sqrt{s}$=189–208 GeV. The search is performed for direct and indirect decays, assuming one coupling at the time to be nonzero. The limit holds for direct decays via $LL\overline{E}$ couplings. Stronger limits are reached for $(\tilde{\nu}_e,\tilde{\nu}_{\mu,\tau})$ for $LL\overline{E}$ indirect (99,78) GeV and for $\overline{UDD}$ direct or indirect (99,70) GeV decays. The MSUGRA limit results from a scan over the MSSM parameter space with the assumption of gaugino and scalar mass unification at the GUT scale, imposing simultaneously the exclusions from neutralino, chargino, sleptons, and squarks analyses. The limit holds for $\overline{UDD}$ couplings and increases to 152.7 GeV for $LL\overline{E}$ couplings.

[154] HEISTER 02F searched for single sneutrino production via $e\gamma \rightarrow \tilde{\nu}_j \ell_k$ mediated by $R\!\!\!/$ $LL\overline{E}$ couplings, decaying directly or indirectly via a $\tilde{\chi}_1^0$ and assuming a single coupling to be nonzero at a time. Final states with three leptons and possible $\not\!\!E_T$ due to neutrinos were selected in the 189–209 GeV data. Limits on the couplings λ_{1jk} as function of the sneutrino mass are shown in Figs. 10–14. The couplings λ_{233} and λ_{233} are not accessible and λ_{121} and λ_{131} are measured with better accuracy in sneutrino resonant production. For all tested couplings, except λ_{133}, the limits are significantly improved compared to the low-energy limits.

[155] ABBIENDI 00 searches for the production of sneutrinos in the case of R-parity violation with $LL\overline{E}$ or $LQ\overline{D}$ couplings, using data from $\sqrt{s}$=183 GeV. They investigate topologies with multiple leptons, jets plus leptons, or multiple jets, assuming one coupling at the time to be non-zero and giving rise to direct or indirect decays. For non-zero $LL\overline{E}$ couplings, they obtain limits on the electron sneutrino mass of 88 GeV for direct decays and of 87 GeV for indirect decays with a low mass χ_1^0. For non-zero $LQ\overline{D}$ couplings, the limits are 86 GeV for indirect decays of $\tilde{\nu}_e$ with a low mass χ_1^0 and 80 GeV for direct decays of $\tilde{\nu}_e$. There exists a region of small Δm, of varying size, for which no limit is obtained, see Fig. 20. It is assumed that tanβ=1.5 and μ=−200 GeV. For muon sneutrinos, direct decays via $LL\overline{E}$ couplings lead to a 66 GeV mass limit and via $LQ\overline{D}$ couplings to a 58 GeV limit.

[156] ABBIENDI 00R studied the effect of s- and t-channel τ or μ sneutrino exchange in $e^+e^- \rightarrow e^+e^-$ at $\sqrt{s}$=130–189 GeV, via the R-parity violating coupling $\lambda_{1i1}L_1L_if_1e_1$ (i=2 or 3). The limits quoted here hold for λ_{1i1} >0.13, and supersede the results of ABBIENDI 99. See Fig. 11 for limits on $m_{\tilde{\nu}}$ versus coupling.

[157] ABBIENDI 00R studied the effect of s-channel τ sneutrino exchange in $e^+e^- \rightarrow \mu^+\mu^-$ at $\sqrt{s}$=130–189 GeV, in presence of the R-parity violating couplings $\lambda_{ij3}L_iL_3e_j$ (i=1 and 2), with λ_{131}=λ_{232}. The limits quoted here hold for λ_{131} > 0.09, and supersede the results of ABBIENDI 99. See Fig. 12 for limits on $m_{\tilde{\nu}}$ versus coupling.

[158] ABREU 00S searches for anomalies in the production cross sections and forward-backward asymmetries of the $\ell^+\ell^-(\gamma)$ final states (ℓ=e,μ,τ) from e^+e^- collisions at $\sqrt{s}$=130–189 GeV. Limits are set on the s- and t-channel exchange of sneutrinos in the presence of $R\!\!\!/$ with $\lambda LL\overline{E}$ couplings. For points between the energies at which data were taken, information is obtained from events in which a photon was radiated. Exclusion limits in the $(\lambda,m_{\tilde{\nu}})$ plane are given in Fig. 5. These limits include and update the results of ABREU 99A.

[159] ABREU 00U searches for the pair production of sneutrinos with a decay involving R-parity violating $LL\overline{E}$ couplings, using data from $\sqrt{s}$=189 GeV. They investigate topologies with multiple leptons, assuming one coupling to be nonzero at the time and giving rise to direct or indirect decays. The limits, valid for each individual flavor, are determined by the indirect decays and assume a neutralino mass limit of 30 GeV, also derived in ABREU 00U. Better limits for specific flavors and for specific $R\!\!\!/$ couplings can be obtained and are discussed in the paper. Supersedes the results of ABREU 00I.

[160] ACCIARRI 00P use the dilepton total cross sections and asymmetries at $\sqrt{s}$=m_Z and $\sqrt{s}$=130–189 GeV data to set limits on the effect of $R\!\!\!/$ $LL\overline{E}$ couplings giving rise to μ or τ sneutrino exchange. See their Fig. 5 for limits on the sneutrino mass versus couplings.

[161] BARATE 00I studied the effect of s-channel and t-channel τ or μ sneutrino exchange in $e^+e^- \rightarrow e^+e^-$ at $\sqrt{s}$= 130–183 GeV, via the R-parity violating coupling $\lambda_{1i1}L_1L_ie_1^c$ (i=2 or 3). The limits quoted here hold for λ_{1i1} > 0.1. See their Fig. 15 for limits as a function of the coupling.

[162] BARATE 00I studied the effect of s-channel τ sneutrino exchange in $e^+e^- \rightarrow \mu^+\mu^-$ at $\sqrt{s}$= 130–183 GeV, in presence of the R-parity violating coupling $\lambda_{ij3}L_iL_3e_f^c$ (i=1 and 2). The limits quoted here hold for $\sqrt{|\lambda_{131}\lambda_{232}|}$ > 0.2. See their Fig. 16 for limits as a function of the coupling.

[163] ABBIENDI 99 studied the effect of t-channel electron sneutrino exchange in $e^+e^- \rightarrow \tau^+\tau^-$ at $\sqrt{s}$=130–183 GeV, in presence of the R-parity violating couplings $\lambda_{131}L_1L_3e_1^c$. The limits quoted here hold for λ_{131} > 0.6.

[164] ACCIARRI 97U studied the effect of the s-channel tau-sneutrino exchange in $e^+e^- \rightarrow e^+e^-$ at $\sqrt{s}$=m_Z and $\sqrt{s}$=130–172 GeV, via the R-parity violating coupling $\lambda_{131}L_1L_if_1e_1^c$. The limits quoted here hold for λ_{131} > 0.05. Similar limits were studied in $e^+e^- \rightarrow \mu^+\mu^-$ together with $\lambda_{232}L_2L_3e_2^c$ coupling.

[165] CARENA 97 studied the constraints on chargino and sneutrino masses from muon $g-2$. The bound can be important for large tanβ.

[166] BUSKULIC 95E looked for $Z \rightarrow \tilde{\nu}\tilde{\nu}$, where $\tilde{\nu} \rightarrow \nu\chi_1^0$ and χ_1^0 decays via R-parity violating interactions into two leptons and a neutrino.

[167] BECK 94 limit can be inferred from limit on Dirac neutrino using $\sigma(\tilde{\nu}) = 4\sigma(\nu)$. Also private communication with H.V. Klapdor-Kleingrothaus.

[168] FALK 94 puts an upper bound on $m_{\tilde{\nu}}$ when $\tilde{\nu}$ is LSP by requiring its relic density does not overclose the Universe.

[169] SATO 91 search for high-energy neutrinos from the sun produced by annihilation of sneutrinos in the sun. Sneutrinos are assumed to be stable and to constitute dark matter in our galaxy. SATO 91 follow the analysis of NG 87, OLIVE 88, and GAISSER 86.

CHARGED SLEPTONS

This section contains limits on charged scalar leptons ($\tilde{\ell}$, with ℓ=e,μ,τ). Studies of width and decays of the Z boson (use is made here of $\Delta\Gamma_{\rm inv}$ < 2.0 MeV, LEP 00) conclusively rule out $m_{\tilde{\ell}_R}$ < 40 GeV (41 GeV for $\tilde{\ell}_L$) , independently of decay modes, for each individual slepton. The limits improve to 43 GeV (43.5 GeV for $\tilde{\ell}_L$) assuming all 3 flavors to be degenerate. Limits on higher mass sleptons depend on model assumptions and on the mass splitting Δm= $m_{\tilde{\ell}} - m_{\tilde{\chi}_1^0}$. The mass and composition of $\tilde{\chi}_1^0$ may affect the selectron production rate in e^+e^- collisions through t-channel exchange diagrams. Production rates are also affected by the potentially large mixing angle of the lightest mass eigenstate $\tilde{\ell}_1$=$\tilde{\ell}_R$ sinθ_ℓ + $\tilde{\ell}_L$ cosθ_ℓ. It is generally assumed that only $\tilde{\tau}$ may have significant mixing. The coupling to the Z vanishes for θ_ℓ=0.82. In the high-energy limit of e^+e collisions the interference between γ and Z exchange leads to a minimal cross section for θ_ℓ=0.91, a value which is sometimes used in the following entries relative to data taken at LEP2. When limits on $m_{\tilde{\ell}_R}$ are quoted, it is understood that limits on $m_{\tilde{\ell}_L}$ are usually at least as strong.

Possibly open decays involving gauginos other than $\tilde{\chi}_1^0$ will affect the detection efficiencies. Unless otherwise stated, the limits presented here result from the study of $\tilde{\ell}^+\tilde{\ell}^-$ production, with production rates and decay properties derived from the MSSM. Limits made obsolete by the recent analyses of e^+e^- collisions at high energies can be found in previous Editions of this Review.

For decays with final state gravitinos ($\tilde{G}$), $m_{\tilde{G}}$ is assumed to be negligible relative to all other masses.

[170] ABBIENDI 04 search for $\tilde{e}_R\tilde{e}_R$ production in acoplanar di-electron final states in the 183–208 GeV data. See Fig. 13 for the dependence of the limits on $m_{\tilde{\chi}_1^0}$ and for the limit at tanβ=35 This limit supersedes ABBIENDI 00G.

[171] ACHARD 04 search for $\tilde{e}_R\tilde{e}_L$ and $\tilde{e}_R\tilde{e}_R$ production in single- and acoplanar di-electron final states in the 192–209 GeV data. Absolute limits on $m_{\tilde{e}_R}$ are derived from a scan over the MSSM parameter space with universal GUT scale gaugino and scalar masses $m_{1/2}$ and m_0, 1 $\leq$ tan$\beta \leq$ 60 and −2 $\leq \mu \leq$ 2 TeV. See Fig. 4 for the dependence of the limits on $m_{\tilde{\chi}_1^0}$. This limit supersedes ACCIARRI 99W.

[172] ABDALLAH 03M looked for acoplanar dielectron + $\not\!\!E$ final states at $\sqrt{s}$ = 189–208 GeV. The limit assumes μ=−200 GeV and tanβ=1.5 in the calculation of the production cross section and B($\tilde{e} \rightarrow e\tilde{\chi}_1^0$). See Fig. 15 for limits in the ($m_{\tilde{e}_R}$, $m_{\tilde{\chi}_1^0}$) plane. These limits include and update the results of ABREU 01

[173] ABDALLAH 03M uses data from $\sqrt{s}$ = 192–208 GeV to obtain limits in the framework of the MSSM with gaugino and sfermion mass universality at the GUT scale. An indirect limit on the mass is derived by constraining the MSSM parameter space by the results from direct searches for neutralinos (including cascade decays) and for sleptons. These limits are valid for values of M_2 < 1 TeV, $|\mu| \leq$ 1 TeV with the $\tilde{\chi}_1^0$ as LSP. The quoted limit is obtained when there is no mixing in the third family. See Fig. 43 for the mass limits as a function of tanβ. These limits update the results of ABREU 00W.

[174] HEISTER 02E looked for acoplanar dielectron + $\not\!\!E_T$ final states from e^+e^- interactions between 183 and 209 GeV. The mass limit assumes $\mu < -200$ GeV and tanβ=2 for the production cross section and B($\tilde{e} \rightarrow e\tilde{\chi}_1^0$)=1. See their Fig. 4 for the dependence of the limit on Δm. These limits include and update the results of BARATE 01.

[175] HEISTER 02N search for $\tilde{e}_R\tilde{e}_L$ and $\tilde{e}_R\tilde{e}_R$ production in single- and acoplanar di-electron final states in the 183–208 GeV data. Absolute limits on $m_{\tilde{e}_R}$ are derived from a scan over the MSSM parameter space with universal GUT scale gaugino and scalar masses $m_{1/2}$ and m_0, 1 $\leq$ tan$\beta \leq$ 50 and −10 $\leq \mu \leq$ 10 TeV. The region of small $|\mu|$, where cascade decays are important, is covered by a search for $\tilde{\chi}_1^0\tilde{\chi}_3^0$ in final states with leptons and possibly photons. Limits on $m_{\tilde{e}_L}$ are derived by exploiting the mass relation between the $\tilde{e}_L$ and $\tilde{e}_R$, based on universal m_0 and $m_{1/2}$. When the constraint from the mass limit of the lightest Higgs from HEISTER 02 is included, the bounds improve to $m_{\tilde{e}_R}$ >77(75) GeV and $m_{\tilde{e}_L}$ >115(115) GeV for a top mass of 175(180) GeV. In the MSUGRA framework with radiative electroweak symmetry breaking, the limits improve further to $m_{\tilde{e}_R}$ >95 GeV and $m_{\tilde{e}_L}$ >152 GeV, assuming a trilinear coupling A_0=0 at the GUT scale. See Figs. 4, 5, 7 for the dependence of the limits on tanβ.

[176] HEISTER 03G searches for the production of selectrons in the case of $R\!\!\!/$ prompt decays with $LL\overline{E}$, $LQ\overline{D}$ or $\overline{UDD}$ couplings at $\sqrt{s}$ = 189–209 GeV. The search is performed for direct and indirect decays, assuming one coupling at a time to be non-zero. The limit holds for indirect decays mediated by $LQ\overline{D}$ couplings with $\Delta m > 10$ GeV. Limits are also given for $LL\overline{E}$ direct ($m_{\tilde{e}_L R} > 96$ GeV) and indirect decays ($m_{\tilde{e}_L R} > 96$ GeV for $m(\tilde{\chi}^0_1) > 23$ GeV from BARATE 98S) and for $\overline{UDD}$ indirect decays ($m_{\tilde{e}_L R} > 94$ GeV with $\Delta m > 10$ GeV). Supersedes the results from BARATE 01B.

[177] ACHARD 02 searches for the production of selectrons in the case of $R\!\!\!/$ prompt decays with $LL\overline{E}$ or $\overline{UDD}$ couplings at $\sqrt{s}$=189–208 GeV. The search is performed for direct and indirect decays, assuming one coupling at the time to be nonzero. The limit holds for direct decays via $LL\overline{E}$ couplings. Stronger limits are reached for $LL\overline{E}$ indirect (79 GeV) and for $\overline{UDD}$ direct or indirect (96 GeV) decays.

[178] BARATE 01 looked for acoplanar dielectron + $\not{E}_T$ final states at 189 to 202 GeV. The limit assumes μ=−200 GeV and tanβ=2 for the production cross section and 100% branching ratio for $\tilde{e} \to e\tilde{\chi}^0_1$. See their Fig. 1 for the dependence of the limit on Δm. These limits include and update the results of BARATE 99Q.

[179] ABBIENDI 00 searches for the production of selectrons in the case of R-parity violation with $LL\overline{E}$ or $LQ\overline{D}$ couplings, using data from $\sqrt{s}$=183 GeV. They investigate topologies with multiple leptons, jets plus leptons, or multiple jets, assuming one coupling at the time to be non-zero and giving rise to direct or indirect decays. For non-zero $LL\overline{E}$ couplings, they obtain limits on the selectron mass of 84 GeV both for direct decays and for indirect decays with a low mass $\tilde{\chi}^0_1$. For non-zero $LQ\overline{D}$ couplings, the limits are 72 GeV for indirect decays of $\tilde{e}_R$ with a low mass $\tilde{\chi}^0_1$ and 76 GeV for direct decays of $\tilde{e}_L$. It is assumed that tanβ=1.5 and μ=−200 GeV.

[180] ABBIENDI 00J looked for acoplanar dielectron + $\not{E}_T$ final states at $\sqrt{s}$= 161–183 GeV. The limit assumes $\mu < -100$ GeV and tanβ=1.5 for the production cross section and decay branching ratios, evaluated within the MSSM, and zero efficiency for decays other than $\tilde{e} \to e\tilde{\chi}^0_1$. See their Fig. 12 for the dependence of the limit on Δm and tanβ.

[181] ABREU 00U studies decays induced by R-parity violating $LL\overline{E}$ couplings, using data from $\sqrt{s}$=189 GeV. They investigate topologies with multiple leptons, assuming one coupling at the time to be nonzero and giving rise to indirect decays. The limits assume a neutralino mass limit of 30 GeV, also derived in ABREU 00U. Updates ABREU 00I.

[182] ABREU 00V use data from $\sqrt{s}$= 130–189 GeV to search for tracks with large impact parameter or visible decay vertices. Limits are obtained as a function of $m_{\tilde{G}}$, from a scan of the GMSB parameters space, after combining these results with the search for slepton pair production in the SUGRA framework from ABREU 01 to cover prompt decays and on stable particle searches from ABREU 00Q. For limits at different $m_{\tilde{G}}$, see their Fig. 12.

[183] BARATE 00G combines the search for acoplanar dileptons, leptons with large impact parameters, kinks, and stable heavy-charged tracks, assuming 3 flavors of degenerate sleptons, produced in the schannel. Data collected at $\sqrt{s}$=189 GeV.

[184] ACCIARRI 99I establish indirect limits on $m_{\tilde{e}_R}$ from the regions excluded in the M_2 versus m_0 plane by their chargino and neutralino searches at $\sqrt{s}$=130–183 GeV. The situations where the $\tilde{\chi}^0_1$ is the LSP (indirect decays) and where a $\tilde{\ell}$ is the LSP (direct decays) were both considered. The weakest limit, quoted above, comes from direct decays with $\overline{UDD}$ couplings; $LL\overline{E}$ couplings or indirect decays lead to a stronger limit.

[185] ACCIARRI 98F looked for acoplanar dielectron+$\not{E}_T$ final states at $\sqrt{s}$=130–172 GeV. The limit assumes μ=−200 GeV, and zero efficiency for decays other than $\tilde{e}_R \to e\tilde{\chi}^0_1$. See their Fig. 6 for the dependence of the limit on Δm.

[186] BARATE 98K looked for $e^+e^-\gamma\gamma + \not{E}$ final states at $\sqrt{s}$= 161–184 GeV. The limit assumes μ=−200 GeV and tanβ=2 for the evaluation of the production cross section. See Fig. 4 for limits on the ($m_{\tilde{e}_R}$,$m_{\tilde{\chi}^0_1}$) plane and for the effect of cascade decays.

[187] BREITWEG 98 used positron+jet events with missing energy and momentum to look for $e^+q \to \tilde{e}\tilde{q}$ via gaugino-like neutralino exchange with decays into $(e\tilde{\chi}^0_1)(q\tilde{\chi}^0_1)$. See paper for dependences in $m(\tilde{q})$, $m(\tilde{\chi}^0_1)$.

[188] AID 96C used positron+jet events with missing energy and momentum to look for $e^+q \to \tilde{e}\tilde{q}$ via neutralino exchange with decays into $(e\tilde{\chi}^0_1)(q\tilde{\chi}^0_1)$. See the paper for dependences on $m_{\tilde{q}}$, $m_{\tilde{\chi}^0_1}$.

[189] ABBIENDI 04 search for $\tilde{\mu}_R\tilde{\mu}_R$ production in acoplanar di-muon final states in the 183–208 GeV data. See Fig. 14 for the dependence of the limits on $m_{\tilde{\chi}^0_1}$ and for the limit at tanβ=35. Under the assumption of 100% branching ratio for $\tilde{\mu}_R \to \mu\tilde{\chi}^0_1$, the limit improves to 94.0 GeV for $\Delta m > 4$ GeV. See Fig. 11 for the dependence of the limits on $m_{\tilde{\chi}^0_1}$ at several values of the branching ratio. This limit supersedes ABBIENDI 00G.

[190] ACHARD 04 search for $\tilde{\mu}_R\tilde{\mu}_R$ production in acoplanar di-muon final states in the 192–209 GeV data. Limits on $m_{\tilde{\mu}_R}$ are derived from a scan over the MSSM parameter space with universal GUT scale gaugino and scalar masses $m_{1/2}$ and m_0, $1 \leq$ tanβ ≤ 60 and $-2 \leq \mu \leq 2$ TeV. See Fig. 4 for the dependence of the limits on $m_{\tilde{\chi}^0_1}$. This limit supersedes ACCIARRI 99W.

[191] ABDALLAH 03M looked for acoplanar dimuon + $\not{E}$ final states at $\sqrt{s}$ = 189–208 GeV. The limit assumes B($\tilde{\mu} \to \mu\tilde{\chi}^0_1$) = 100%. See Fig. 16 for limits on the ($m_{\tilde{\mu}_R}$, $m_{\tilde{\chi}^0_1}$) plane. These limits include and update the results of ABREU 01.

[192] ABDALLAH 03M uses data from $\sqrt{s}$ = 192–208 GeV to obtain limits in the framework of the MSSM with gaugino and sfermion mass universality at the GUT scale. An indirect limit on the mass is derived by constraining the MSSM parameter space by the results from direct searches for neutralinos (including cascade decays) and for sleptons. These limits are valid for values of $M_2 < 1$ TeV, $|\mu| \leq 1$ TeV with the $\tilde{\chi}^0_1$ as LSP. The quoted limit is obtained when there is no mixing in the third family. See Fig. 43 for the mass limits as a function of tanβ. These limits update the results of ABREU 00W.

[193] HEISTER 02E looked for acoplanar dimuon + $\not{E}_T$ final states from e^+e^- interactions between 183 and 209 GeV. The mass limit assumes B($\tilde{\mu} \to \mu\tilde{\chi}^0_1$)=1. See their Fig. 4 for the dependence of the limit on Δm. These limits include and update the results of BARATE 01.

[194] HEISTER 03G searches for the production of smuons in the case of $R\!\!\!/$ prompt decays with $LL\overline{E}$, $LQ\overline{D}$ or $\overline{UDD}$ couplings at $\sqrt{s}$ = 189–209 GeV. The search is performed for direct and indirect decays, assuming one coupling at a time to be non-zero. The limit holds for direct decays mediated by $R\!\!\!/$ $LQ\overline{D}$ couplings and improves to 90 GeV for indirect decays (for $\Delta m > 10$ GeV). Limits are also given for $LL\overline{E}$ direct ($m_{\tilde{\mu}R} > 87$ GeV) and indirect decays ($m_{\tilde{\mu}R} > 96$ GeV for $m(\tilde{\chi}^0_1) > 23$ GeV from BARATE 98S) and for $\overline{UDD}$ indirect decays ($m_{\tilde{\mu}R} > 85$ GeV for $\Delta m > 10$ GeV). Supersedes the results from BARATE 01B.

[195] ABAZOV 02H looked in 94 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV for events with at least 2 muons and 2 jets for s-channel production of $\tilde{\mu}$ or $\tilde{\nu}$ and subsequent decay via $R\!\!\!/$ couplings $LQ\overline{D}$. A scan over the MSUGRA parameters is performed to exclude regions of the (m_0,$m_{1/2}$) plane, examples being shown in Fig. 2.

[196] ACHARD 02 searches for the production of smuons in the case of $R\!\!\!/$ prompt decays with $LL\overline{E}$ or $\overline{UDD}$ couplings at $\sqrt{s}$=189–208 GeV. The search is performed for direct and indirect decays, assuming one coupling at the time to be nonzero. The limit holds for direct decays via $LL\overline{E}$ couplings. Stronger limits are reached for $LL\overline{E}$ indirect (87 GeV) and for $\overline{UDD}$ direct or indirect (86 GeV) decays.

[197] BARATE 01 looked for acoplanar dimuon + $\not{E}_T$ final states at 189 to 202 GeV. The limit assumes 100% branching ratio for $\tilde{\mu} \to \mu\tilde{\chi}^0_1$. See their Fig. 1 for the dependence of the limit on Δm. These limits include and update the results of BARATE 99Q.

[198] ABBIENDI 00 searches for the production of smuons in the case of R-parity violation with $LL\overline{E}$ or $LQ\overline{D}$ couplings, using data from $\sqrt{s}$=183 GeV. They investigate topologies with multiple leptons, jets plus leptons, or multiple jets, assuming one coupling at the time to be non-zero and giving rise to direct or indirect decays. For non-zero $LL\overline{E}$ couplings, they obtain limits on the smuon mass of 66 GeV for direct decays and of 74 GeV for indirect decays with a low mass $\tilde{\chi}^0_1$. For non-zero $LQ\overline{D}$ couplings, the limits are 50 GeV for indirect decays of $\tilde{\mu}_R$ with a low mass $\tilde{\chi}^0_1$ and 64 GeV for direct decays of $\tilde{\mu}_L$. It is assumed that tanβ=1.5 and μ=−200 GeV.

[199] ABBIENDI 00J looked for acoplanar dimuon + $\not{E}_T$ final states at $\sqrt{s}$= 161–183 GeV. The limit assumes B($\tilde{\mu} \to \mu\tilde{\chi}^0_1$)=1. Using decay branching ratios derived from the MSSM, a lower limit of 65 GeV is obtained for $\mu < -100$ GeV and tanβ=1.5. See their Figs. 10 and 13 for the dependence of the limit on the branching ratio and on Δm.

[200] ABREU 00U studies decays induced by R-parity violating $LL\overline{E}$ couplings, using data from $\sqrt{s}$=189 GeV. They investigate topologies with multiple leptons, assuming one coupling at the time to be nonzero and giving rise to indirect decays. The limits, valid for each individual flavor, assume a neutralino mass limit of 30 GeV, also derived in ABREU 00U. Updates ABREU 00I.

[201] ABREU 00V use data from $\sqrt{s}$= 130–189 GeV to search for tracks with large impact parameter or visible decay vertices. Limits are obtained as function of $m_{\tilde{G}}$, after combining these results with the search for slepton pair production in the SUGRA framework from ABREU 01 to cover prompt decays and on stable particle searches from ABREU 00Q. For limits at different $m_{\tilde{G}}$, see their Fig. 12.

[202] BARATE 98K looked for $\mu^+\mu^-\gamma\gamma + \not{E}$ final states at $\sqrt{s}$= 161–184 GeV. See Fig. 4 for limits on the ($m_{\tilde{\mu}_R}$,$m_{\tilde{\chi}^0_1}$) plane and for the effect of cascade decays.

[203] ABBIENDI 04 search for $\tilde{\tau}\tilde{\tau}$ production in acoplanar di-tau final states in the 183–208 GeV data. See Fig. 15 for the dependence of the limits on $m_{\tilde{\chi}_1^0}$ and for the limit at tanβ=35. Under the assumption of 100% branching ratio for $\tilde{\tau}_R \rightarrow \tau\tilde{\chi}_1^0$, the limit improves to 89.8 GeV for $\Delta m > 8$ GeV. See Fig. 12 for the dependence of the limits on $m_{\tilde{\chi}_1^0}$ at several values of the branching ratio and for their dependence on θ_τ. This limit supersedes ABBIENDI 00G.

[204] ACHARD 04 search for $\tilde{\tau}\tilde{\tau}$ production in acoplanar di-tau final states in the 192–209 GeV data. Limits on $m_{\tilde{\tau}_R}$ are derived from a scan over the MSSM parameter space with universal GUT scale gaugino and scalar masses $m_{1/2}$ and m_0, $1 \leq \tan\beta \leq 60$ and $-2 \leq \mu \leq 2$ TeV. See Fig. 4 for the dependence of the limits on $m_{\tilde{\chi}_1^0}$.

[205] ABDALLAH 03M looked for acoplanar ditaus + $\not{E}$ final states at $\sqrt{s}$ = 130–208 GeV. A dedicated search was made for low mass $\tilde{\tau}$s decoupling from the Z^0. The limit assumes B($\tilde{\tau} \rightarrow \tau\tilde{\chi}_1^0$) = 100%. See Fig. 20 for limits on the ($m_{\tilde{\tau}}$,$m_{\tilde{\chi}_1^0}$) plane and as function of the $\tilde{\chi}_1^0$ mass and of the branching ratio. The limit in the low-mass region improves to 29.6 and 31.1 GeV for $\tilde{\tau}_R$ and $\tilde{\tau}_L$, respectively, at $\Delta m > m_\tau$. The limit in the high-mass region improves to 84.7 GeV for $\tilde{\tau}_R$ and $\Delta m > 15$ GeV. These limits include and update the results of ABREU 01.

[206] HEISTER 02E looked for acoplanar ditau + $\not{E}_T$ final states from e^+e^- interactions between 183 and 209 GeV. The mass limit assumes B($\tilde{\tau} \rightarrow \tau\tilde{\chi}_1^0$)=1. See their Fig. 4 for the dependence of the limit on Δm. These limits include and update the results of BARATE 01.

[207] ABDALLAH 03D use data from $\sqrt{s}$= 130-208 GeV to search for tracks with large impact parameter or visible decay vertices and for heavy charged stable particles. Limits are obtained as function of m($\tilde{G}$), after combining these results with the search for slepton pair production in the SUGRA framework from ABDALLAH 03M to cover prompt decays. The above limit is reached for the stau decaying promptly, m($\tilde{G}$) < 6 eV, and is computed for stau mixing yielding the minimal cross section. Stronger limits are obtained for longer lifetimes, See their Fig. 9. Supersedes the results of ABREU 01G.

[208] HEISTER 03G searches for the production of staus in the case of $\not{R}$ prompt decays with $LL\overline{E}$, $LQ\overline{D}$ or $\overline{UDD}$ couplings at $\sqrt{s}$ = 189–209 GeV. The search is performed for direct and indirect decays, assuming one coupling at a time to be non-zero. The limit holds for indirect decays mediated by $\not{R}$ $\overline{UDD}$ couplings with $\Delta m > 10$ GeV. Limits are also given for $LL\overline{E}$ direct ($m_{\tilde{\tau}_R} > 87$ GeV) and indirect decays ($m_{\tilde{\tau}_R} > 95$ GeV for $m(\tilde{\chi}_1^0) > 23$ GeV from BARATE 98S) and for $LQ\overline{D}$ indirect decays ($m_{\tilde{\tau}_R} > 76$ GeV). Supersedes the results from BARATE 01B.

[209] ACHARD 02 searches for the production of staus in the case of $\not{R}$ prompt decays with $LL\overline{E}$ or $\overline{UDD}$ couplings at $\sqrt{s}$=189–208 GeV. The search is performed for direct and indirect decays, assuming one coupling at the time to be nonzero. The limit holds for indirect decays via $LL\overline{E}$ couplings. Stronger limits are reached for $LL\overline{E}$ indirect (86 GeV) and for $\overline{UDD}$ direct or indirect (75 GeV) decays.

[210] HEISTER 02R search for signals of GMSB in the 189–209 GeV data. For the $\tilde{\chi}_1^0$ NLSP scenario, they looked for topologies consisting of $\gamma\gamma\not{E}$ or a single γ not pointing to the interaction vertex. For the $\tilde{\ell}$ NLSP case, the topologies consist of $\ell\ell\not{E}$, including leptons with large impact parameters, kinks, or stable particles. Limits are derived from a scan over the GMSB parameters (see their Table 5 for the ranges). The limit remains valid whichever is the NLSP. The absolute mass bound on the $\tilde{\chi}_1^0$ for any lifetime includes indirect limits from the slepton search HEISTER 02E preformed within the MSUGRA framework. A bound for any NLSP and any lifetime of 77 GeV has also been derived by using the constraints from the neutral Higgs search in HEISTER 02. In the co-NLSP scenario, limits $m_{\tilde{e}_R} > 83$ GeV (neglecting t-channel exchange) and $m_{\tilde{\mu}_R} > 88$ GeV are obtained independent of the lifetime. Supersedes the results from BARATE 00G.

[211] BARATE 01 looked for acoplanar ditau + $\not{E}_T$ final states at 189 to 202 GeV. A slight excess (with 1.2% probability) of events is observed relative to the expected SM background. The limit assumes 100% branching ratio for $\tilde{\tau} \rightarrow \tau\tilde{\chi}_1^0$. See their Fig. 1 for the dependence of the limit on Δm. These limits include and update the results of BARATE 99Q.

[212] ABBIENDI 00 searches for the production of staus in the case of R-parity violation with $LL\overline{E}$ or $LQ\overline{D}$ couplings, using data from $\sqrt{s}$=183 GeV. They investigate topologies with multiple leptons, jets plus leptons, or multiple jets, assuming one coupling at the time to be non-zero and giving rise to direct or indirect decays. For non-zero $LL\overline{E}$ couplings, they obtain limits on the stau mass of 66 GeV both for direct decays and for indirect decays with a low mass χ_1^0. For non-zero $LQ\overline{D}$ couplings, the limits are 66 GeV for indirect decays of $\tilde{\tau}_R$ with a low mass χ_1^0 and 63 GeV for direct decays of $\tilde{\tau}_L$. It is assumed that tanβ=1.5 and μ=– 200 GeV.

[213] ABBIENDI 00J looked for acoplanar ditau + $\not{E}_T$ final states at $\sqrt{s}$= 161–183 GeV. The limit assumes B($\tilde{\tau} \rightarrow \tau\tilde{\chi}_1^0$)=1. Using decay branching ratios derived from the MSSM, a lower limit of 60 GeV at Δm >9 GeV is obtained for $\mu < -100$ GeV and tanβ=1.5. See their Figs. 11 and 14 for the dependence of the limit on the branching ratio and on Δm.

[214] ABREU 00U studies decays induced by R-parity violating $LL\overline{E}$ couplings, using data from $\sqrt{s}$=189 GeV. They investigate topologies with multiple leptons, assuming one coupling at the time to be nonzero and giving rise to indirect decays. The limits, valid for each individual flavor, assume a neutralino mass limit of 30 GeV, also derived in ABREU 00U. Updates ABREU 00I.

[215] ABREU 00V use data from $\sqrt{s}$= 130–189 GeV to search for tracks with large impact parameter or visible decay vertices. Limits are obtained as function of $m_{\tilde{G}}$, after combining these results with the search for slepton pair production in the SUGRA framework from ABREU 01 to cover prompt decays and on stable particle searches from ABREU 00Q. The above limit assumes the degeneracy of stau and smuon. For limits at different $m_{\tilde{G}}$, see their Fig. 12.

[216] ABREU 00V use data from $\sqrt{s}$= 130–189 GeV to search for tracks with large impact parameter or visible decay vertices. Limits are obtained as function of $m_{\tilde{G}}$, after combining these results with the search for slepton pair production in the SUGRA framework from ABREU 01 to cover prompt decays and on stable particle searches from ABREU 00Q. The above limit is reached for the stau mixing yielding the minimal cross section and decaying promptly. Stronger limits are obtained for longer lifetimes or for $\tilde{\tau}_R$; see their Fig. 11. For $10 \leq m_{\tilde{G}} \leq 310$ eV, the whole range $2 \leq m_{\tilde{\tau}_1} \leq 80$ GeV is excluded. Supersedes the results of ABREU 99C and ABREU 99F.

[217] BARATE 98K looked for $\tau^+\tau^-\gamma\gamma + \not{E}$ final states at $\sqrt{s}$= 161–184 GeV. See Fig. 4 for limits on the ($m_{\tilde{\tau}_R}$,$m_{\tilde{\chi}_1^0}$) plane and for the effect of cascade decays.

Degenerate Charged Sleptons

Unless stated otherwise in the comment lines or in the footnotes, the following limits assume 3 families of degenerate charged sleptons.

VALUE (GeV)	CL%	DOCUMENT ID		TECN	COMMENT

		[222] ABREU	01	DLPH	$\tilde{\ell} \rightarrow \ell\tilde{\chi}_2^0$, $\tilde{\chi}_2^0 \rightarrow \gamma\tilde{\chi}_1^0$, ℓ=e,μ
>68.8	95	[223] ACCIARRI	01	L3	$\tilde{\ell}_R$, $\not{R}$, $0.7 \leq \tan\beta \leq 40$
>84	95	[224,225] ABREU	00V	DLPH	$\tilde{\ell}_R\tilde{\ell}_R$ ($\tilde{\ell}_R \rightarrow \ell\tilde{G}$), $m_{\tilde{G}}>9$ eV

[218] BARATE 01 looked for acoplanar dilepton + $\not{E}_T$ and single electron (for $\tilde{e}_R\tilde{e}_L$) final states at 189 to 202 GeV. The limit assumes μ=– 200 GeV and tanβ=2 for the production cross section and decay branching ratios, evaluated within the MSSM, and zero efficiency for decays other than $\tilde{\ell} \rightarrow \ell\tilde{\chi}_1^0$. The slepton masses are determined from the GUT relations without stau mixing. See their Fig. 1 for the dependence of the limit on Δm.

[219] ABDALLAH 03D use data from $\sqrt{s}$= 130-208 GeV to search for tracks with large impact parameter or visible decay vertices and for heavy charged stable particles. Limits are obtained as function of m($\tilde{G}$), after combining these results with the search for slepton pair production in the SUGRA framework from ABDALLAH 03M to cover prompt decays The above limit is reached for prompt decays and assumes the degeneracy of the sleptons. For limits at different m($\tilde{G}$), see their Fig. 9. Supersedes the results of ABREU 01G.

[220] ACHARD 02 searches for the production of sparticles in the case of $\not{R}$ prompt decays with $LL\overline{E}$ or $\overline{UDD}$ couplings at $\sqrt{s}$=189–208 GeV. The search is performed for direct and indirect decays, assuming one coupling at the time to be nonzero. The MSUGRA limit results from a scan over the MSSM parameter space with the assumption of gaugino and scalar mass unification at the GUT scale and no mixing in the slepton sector, imposing simultaneously the exclusions from neutralino, chargino, sleptons, and squarks analyses. The limit holds for $LL\overline{E}$ couplings and increases to 88.7 GeV for $\overline{UDD}$ couplings. For L3 limits from $LQ\overline{D}$ couplings, see ACCIARRI 01.

[221] ABBIENDI 01 looked for final states with $\gamma\gamma\not{E}$, $\ell\ell\not{E}$, with possibly additional activity and four leptons + $\not{E}$ to search for prompt decays of $\tilde{\chi}_1^0$ or $\tilde{\ell}_1$ in GMSB. They derive limits in the plane ($m_{\tilde{\chi}_1^0}$,$m_{\tilde{\tau}_1}$), see Fig. 6, allowing either the $\tilde{\chi}_1^0$ or a $\tilde{\ell}_1$ to be the NLSP. Two scenarios are considered: tanβ=2 with the 3 sleptons degenerate in mass and tanβ=20 where the $\tilde{\tau}_1$ is lighter than the other sleptons. Data taken at $\sqrt{s}$=189 GeV. For tanβ=20, the obtained limits are $m_{\tilde{\tau}_1} > 69$ GeV and $m_{\tilde{e}_1,\tilde{\mu}_1} > 88$ GeV.

[222] ABREU 01 looked for acoplanar dilepton + diphoton + $\not{E}$ final states from $\tilde{\ell}$ cascade decays at $\sqrt{s}$=130–189 GeV. See Fig. 9 for limits on the (μ,M_2) plane for $m_{\tilde{\ell}}$=80 GeV, tanβ=1.0, and assuming degeneracy of $\tilde{\mu}$ and $\tilde{e}$.

[223] ACCIARRI 01 searches for multi-lepton and/or multi-jet final states from $\not{R}$ prompt decays with $LL\overline{E}$, $LQ\overline{D}$, or $\overline{UDD}$ couplings at $\sqrt{s}$=189 GeV. The search is performed for direct and indirect decays of neutralinos, charginos, and scalar leptons, with the $\tilde{\chi}_1^0$ or a $\tilde{\ell}$ as LSP and assuming one coupling to be nonzero at a time. Mass limits are derived using simultaneously the constraints from the neutralino, chargino, and slepton analyses; and the Z^0 width measurements from ACCIARRI 00C in a scan of the parameter space assuming MSUGRA with gaugino and scalar mass universality. Updates and supersedes the results from ACCIARRI 99I.

[224] ABREU 00V use data from $\sqrt{s}$= 130–189 GeV to search for tracks with large impact parameter or visible decay vertices. Limits are obtained as function of $m_{\tilde{G}}$, after combining these results with the search for slepton pair production in the SUGRA framework from ABREU 01 to cover prompt decays and on stable particle searches from ABREU 00Q. For limits at different $m_{\tilde{G}}$, see their Fig. 12.

[225] The above limit assumes the degeneracy of stau and smuon.

Long-lived $\tilde{\ell}$ (Slepton) MASS LIMIT

Limits on scalar leptons which leave detector before decaying. Limits from Z decays are independent of lepton flavor. Limits from continuum e^+e^- annihilation are also independent of flavor for smuons and staus. Selectron limits from e^+e^- collisions in the continuum depend on MSSM parameters because of the additional neutralino exchange contribution.

VALUE (GeV)	CL%	DOCUMENT ID		TECN	COMMENT
>98	95	[226] ABBIENDI	03L	OPAL	$\tilde{\mu}_R$, $\tilde{\tau}_R$
none 2–87.5	95	[227] ABREU	00Q	DLPH	$\tilde{\mu}_R$, $\tilde{\tau}_R$
>81.2	95	[228] ACCIARRI	99H	L3	$\tilde{\mu}_R$, $\tilde{\tau}_R$
>81	95	[229] BARATE	98K	ALEP	$\tilde{\mu}_R$, $\tilde{\tau}_R$

[226] ABBIENDI 03L used e^+e^- data at $\sqrt{s}$ = 130–209 GeV to select events with two high momentum tracks with anomalous dE/dx. The excluded cross section is compared to the theoretical expectation as a function of the heavy particle mass in their Fig. 3. The limit improves to 98.5 GeV for $\tilde{\mu}_L$ and $\tilde{\tau}_L$. The bounds are valid for colorless spin 0 particles with lifetimes longer than 10^{-6} s. Supersedes the results from ACKERSTAFF 98P.

[227] ABREU 00Q searches for the production of pairs of heavy, charged stable particles in e^+e^- annihilation at $\sqrt{s}$= 130–189 GeV. The upper bound improves to 88 GeV for $\tilde{\mu}_L$, $\tilde{\tau}_L$. These limits include and update the results of ABREU 98P.

[228] ACCIARRI 99H searched for production of pairs of back-to-back heavy charged particles at $\sqrt{s}$=130–183 GeV. The upper bound improves to 82.2 GeV for $\tilde{\mu}_L$, $\tilde{\tau}_L$.

[229] The BARATE 98K mass limit improves to 82 GeV for $\tilde{\mu}_L$,$\tilde{\tau}_L$. Data collected at $\sqrt{s}$=161–184 GeV.

$\tilde{q}$ (Squark) MASS LIMIT

For $m_{\tilde{q}} > 60$–70 GeV, it is expected that squarks would undergo a cascade decay via a number of neutralinos and/or charginos rather than undergo a direct decay to photinos as assumed by some papers. Limits obtained when direct decay is assumed are usually higher than limits when cascade decays are included.

Limits from e^+e^- collisions depend on the mixing angle of the lightest mass eigenstate $\tilde{q}_1 = \tilde{q}_R \sin\theta_q + \tilde{q}_L \cos\theta_q$. It is usually assumed that only the sbottom and stop squarks have non-trivial mixing angles (see the stop and sbottom sections). Here, unless otherwise noted, squarks are always taken to be either left/right degenerate, or purely of left or right type. Data from Z decays have set squark mass limits above 40 GeV, in the case of $\tilde{q} \to q\tilde{\chi}_1$ decays if $\Delta m = m_{\tilde{q}} - m_{\tilde{\chi}^0_1} \gtrsim 5$ GeV. For smaller values of Δm, current constraints on the invisible width of the Z ($\Delta\Gamma_{\rm inv} < 2.0$ MeV, LEP 00) exclude $m_{\tilde{u}_{L,R}} < 44$ GeV, $m_{\tilde{d}_R} < 33$ GeV, $m_{\tilde{d}_L} < 44$ GeV and, assuming all squarks degenerate, $m_{\tilde{q}} < 45$ GeV.

Limits made obsolete by the most recent analyses of e^+e^-, $p\overline{p}$, and ep collisions can be found in previous Editions of this *Review*.

[230] ACHARD 04 search for the production of $\tilde{q}\bar{\tilde{q}}$ of the first two generations in acoplanar di-jet final states in the 192–209 GeV data. Degeneracy of the squark masses is assumed either for both left and right squarks or for right squarks only, as well as $B(\tilde{q} \to q\tilde{\chi}^0_1) = 1$ See Fig. 7 for the dependence of the limits on $m_{\tilde{\chi}^0_1}$. This limit supersedes ACCIARRI 99V.

[231] ABBOTT 01D looked in $\sim 108\ pb^{-1}$ of $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV for events with ee, $\mu\mu$, or $e\mu$ accompanied by at least 2 jets and $\not\!\!E_T$. Excluded regions are obtained in the MSUGRA framework from a scan over the parameters $0 < m_0 < 300$ GeV, $10 < m_{1/2} < 110$ GeV, and $1.2 < \tan\beta < 10$.

[232] BARATE 01 looked for acoplanar dijets + $\not\!\!E_T$ final states at 189 to 202 GeV. The limit assumes $B(\tilde{q} \to q\tilde{\chi}^0_1) = 1$, with $\Delta m = m_{\tilde{q}} - m_{\tilde{\chi}^0_1}$. It applies to $\tan\beta = 4$, $\mu = -400$ GeV. See their Fig. 2 for the exclusion in the $(m_{\tilde{q}}, m_{\tilde{g}})$ plane. These limits include and update the results of BARATE 99Q.

[233] ABBOTT 99L consider events with three or more jets and large $\not\!\!E_T$. Spectra and decay rates are evaluated in the framework of minimal Supergravity, assuming five flavors of degenerate squarks, and scanning the space of the universal gaugino ($m_{1/2}$) and scalar (m_0) masses. See their Figs. 2–3 for the dependence of the limit on the relative value of $m_{\tilde{q}}$ and $m_{\tilde{g}}$.

[234] ABE 96D searched for production of gluinos and five degenerate squarks in final states containing a pair of leptons, two jets, and missing E_T. The two leptons arise from the semileptonic decays of charginos produced in the cascade decays. The limit is derived for fixed $\tan\beta = 4.0$, $\mu = -400$ GeV, and $m_{H^+} = 500$ GeV, and with the cascade decays of the squarks and gluinos calculated within the framework of the Minimal Supergravity scenario.

[235] ADLOFF 03 looked for the s-channel production of squarks via $\not{R}\ L\overline{Q}\overline{D}$ couplings in 117.2 pb^{-1} of e^+p data at $\sqrt{s}$ = 301 and 319 GeV and of e^-p data at $\sqrt{s}$ = 319 GeV. The comparison of the data with the SM differential cross section allows limits to be set on couplings for processes mediated through contact interactions. They obtain lower bounds on the value of $m_{\tilde{q}}/\lambda'$ of 710 GeV for the process $e^+\tilde{u} \to \bar{d}^k$ (and charge conjugate), mediated by λ'_{11k}, and of 430 GeV for the process $e^+d \to \bar{u}^j$ (and charge conjugate), mediated by λ'_{1j1}.

[236] CHEKANOV 03B used 131.5 pb^{-1} of e^+p and e^-p data taken at 300 and 318 GeV to look for narrow resonances in the eq or νq final states. Such final states may originate from $L\overline{Q}\overline{D}$ couplings with non-zero λ'_{1j1} (leading to $\tilde{u}_j$) or λ'_{11k} (leading to $\tilde{d}_k$). See their Fig. 8 and explanations in the text for limits. The quoted mass bound assumes that only direct squark decays contribute.

[237] HEISTER 03G searches for the production of squarks in the case of $\not{R}$ prompt decays with $\overline{UDD}$ direct couplings at at $\sqrt{s} = 189$–209 GeV.

[238] ABAZOV 02F looked in 77.5 pb^{-1} of $p\overline{p}$ collisions at 1.8 TeV for events with $\geq 2\mu + \geq$ 4jets, originating from associated production of squarks followed by an indirect $\not{R}$ decay (of the $\tilde{\chi}^0_1$) via $L\overline{Q}\overline{D}$ couplings of the type λ'_{2jk} where j=1,2 and k=1,2,3. Bounds are obtained in the MSUGRA scenario by a scan in the range $0 \leq M_0 \leq 400$ GeV, $60 \leq m_{1/2} \leq 120$ GeV for fixed values $A_0 = 0$, $\mu < 0$, and $\tan\beta$=2 or 6. The bounds are weaker for $\tan\beta$=6. See Figs. 2,3 for the exclusion contours in $m_{1/2}$ versus m_0 for $\tan\beta$=2 and 6, respectively.

[239] ABAZOV 02G search for associated production of gluinos and squarks in 92.7 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV, using events with one electron, ≥ 4 jets, and large $\not\!\!E_T$. The results are compared to a MSUGRA scenario with $\mu < 0$, $A_0 = 0$, and $\tan\beta = 3$ and allow to exclude a region of the $(m_0, m_{1/2})$ shown in Fig. 11.

[240] ABBIENDI 02 looked for events with an electron or neutrino and a jet in e^+e^- at 189 GeV. Squarks (or leptoquarks) could originate from a $L\overline{Q}\overline{D}$ coupling of an electron with a quark from the fluctuation of a virtual photon. Limits on the couplings λ'_{1jk} as a function of the squark mass are shown in Figs. 8–9, assuming that only direct squark decays contribute.

[241] ABBIENDI 02B looked for events with an electron or neutrino and a jet in e^+e^- at 189–209 GeV. Squarks (or leptoquarks) could originate from a $L\overline{Q}\overline{D}$ coupling of an electron with a quark from the fluctuation of a virtual photon. Limits on the couplings λ'_{1jk} as a function of the squark mass are shown in Fig. 4, assuming that only direct squark decays contribute. The quoted limits are read off from Fig. 4. Supersedes the results of ABBIENDI 02.

[242] ACHARD 02 searches for the production of squarks in the case of $\not{R}$ prompt decays with UDD couplings at $\sqrt{s}$=189–208 GeV. The search is performed for direct and indirect decays, assuming one coupling at the time to be nonzero. The limit holds for indirect decays. Stronger limits are reached for ($\tilde{u}_R$,$\tilde{d}_R$) direct (80,56) GeV and ($\tilde{u}_L$,$\tilde{d}_L$) direct or indirect (87,86) GeV decays.

[243] CHEKANOV 02 search for lepton flavor violating processes $e^+p \to \ell X$, where $\ell = \mu$ or τ with high p_T, in 47.7 pb^{-1} of e^+p collisions at 300 GeV. Such final states may originate from $LQ\overline{D}$ couplings with simultaneously nonzero λ'_{1jk} and λ'_{ijk} (i=2 or 3). The quoted mass bound assumes that only direct squark decays contribute.

[244] ADLOFF 01B searches for squark exchange in 37 pb^{-1} of e^+p collisions, mediated by $\not{R}$ couplings $LQ\overline{D}$ and leading to several final states with leptons and jets from direct or indirect decays. The 7 decay topologies considered cover almost all branching fractions. Limits are derived on λ'_{1j1}, as a function of the squark mass from a scan over the parameters 70<M_2 <350 GeV, $-300 < \mu < 300$ GeV, assuming mass degeneracy for the squarks, a slepton mass of 90 GeV, and tanβ=2. Similar limits obtained under more constrained model assumptions are discussed in the paper. These results supersede AID 96.

[245] BARATE 01B searches for the production of squarks in the case of $\not{R}$ prompt decays with $LL\overline{E}$ indirect or $\overline{UDD}$ direct couplings at $\sqrt{s}$=189–202 GeV. The limit holds for direct decays mediated by $\not{R}$ $\overline{UDD}$ couplings. Limits are also given for $LL\overline{E}$ indirect decays ($m_{\tilde{u}_R} > 90$ GeV and $m_{\tilde{d}_R} > 89$ GeV). Supersedes the results from BARATE 00H.

[246] BREITWEG 01 searches for squark production in 47.7 pb^{-1} of e^+p collisions, mediated by $\not{R}$ couplings $LQ\overline{D}$ and leading to final states with $\tilde{\nu}$ and ≥ 1 jet, complementing the e^+X final states of BREITWEG 00E. Limits are derived on $\lambda'\sqrt{\beta}$, where β is the branching fraction of the squarks into e^+q+$\overline{\nu}q$, as function of the squark mass, see their Fig. 15. The quoted mass limit assumes that only direct squark decays contribute.

[247] ABBOTT 00C searched in $\sim$ 94 pb^{-1} of $p\overline{p}$ collisions for events with $\mu\mu$+jets, originating from associated production of leptoquarks. The results can be interpreted as limits on production of squarks followed by direct $\not{R}$ decay via $\lambda'_{2jk}L_2Q_jd^c_k$ couplings. Bounds are obtained on the cross section for branching ratios of 1 and of 1/2, see their Fig. 4. The former yields the limit on the $\tilde{u}_L$. The latter is combined with the bound of ABBOTT 99J from the $\mu\nu$+jets channel and of ABBOTT 98E and ABBOTT 98J from the $\nu\nu$+jets channel to yield the limit on $\tilde{d}_R$.

[248] ACCIARRI 00P studied the effect on hadronic cross sections of t-channel down-type squark exchange via R-parity violating coupling $\lambda'_{1jk}L_1Q_jd^c_k$. The limit here refers to the case j=1,2, and holds for λ'_{1jk}=0.3. Data collected at $\sqrt{s}$=130–189 GeV, superseding the results of ACCIARRI 98J.

[249] AFFOLDER 00K searched in $\sim$ 88 pb^{-1} of $p\overline{p}$ collisions for events with 2–3 jets, at least one being b-tagged, large $\not{E}_T$ and no high p_T leptons. Such $\nu\nu$+b-jets events would originate from associated production of squarks followed by direct $\not{R}$ decay via $\lambda'_{ij3}L_iQ_jd^c_3$ couplings. Bounds are obtained on the production cross section assuming zero branching ratio to charged leptons.

[250] BARATE 00I studied the effect on hadronic cross sections and charge asymmetries of t-channel down-type squark exchange via R-parity violating coupling $\lambda'_{1jk}L_1Q_jd^c_k$. The limit here refers to the case j=1,2, and holds for λ'_{1jk}=0.3. A 50 GeV limit is found for up-type squarks with k=3. Data collected at $\sqrt{s}$= 130–183 GeV.

[251] BREITWEG 00E searches for squark exchange in e^+p collisions, mediated by $\not{R}$ couplings $LQ\overline{D}$ and leading to final states with an identified e^+ and ≥ 1 jet. The limit applies to up-type squarks of all generations, and assumes B($\tilde{q} \to qe$)=1.

[252] ABBOTT 99 searched for $\gamma\not{E}_T + \geq 2$ jet final states, and set limits on $\sigma(p\overline{p} \to \tilde{q}$+X)·B($\tilde{q} \to \gamma\not{E}_T$X). The quoted limits correspond to $m_{\tilde{g}} \geq m_{\tilde{q}}$, with B($\tilde{\chi}^0_2 \to \tilde{\chi}^0_1\gamma$)=1 and B($\tilde{\chi}^0_1 \to \tilde{G}\gamma$)=1, respectively. They improve to 310 GeV (360 GeV in the case of $\gamma\tilde{G}$ decay) for $m_{\tilde{g}}$=$m_{\tilde{q}}$.

[253] ABBOTT 99K uses events with an electron pair and four jets to search for the decay of the $\tilde{\chi}^0_1$ LSP via $\not{R}$ $LQ\overline{D}$ couplings. The particle spectrum and decay branching ratios are taken in the framework of minimal supergravity. An excluded region at 95% CL is obtained in the (m_0,$m_{1/2}$) plane under the assumption that A_0=0, $\mu < 0$, tanβ=2 and any one of the couplings $\lambda'_{1jk} > 10^{-3}$ (j=1,2 and k=1,2,3) and from which the above limit is computed. For equal mass squarks and gluinos, the corresponding limit is 277 GeV. The results are essentially independent of A_0, but the limit deteriorates rapidly with increasing tanβ or $\mu > 0$.

[254] ABE 99M looked in 107 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV for events with like sign dielectrons and two or more jets from the sequential decays $\tilde{q} \to q\tilde{\chi}^0_1$ and $\tilde{\chi}^0_1 \to eq\overline{q}'$, assuming $\not{R}$ coupling $L_1Q_jD^c_k$, with j=2,3 and k=1,2,3. They assume five degenerate squark flavors, B($\tilde{q} \to q\tilde{\chi}^0_1$)=1, B($\tilde{\chi}^0_1 \to eq\overline{q}'$)=0.25 for both e^+ and e^-, and $m_{\tilde{g}} \geq$ 200 GeV. The limit is obtained for $m_{\tilde{\chi}^0_1} \geq m_{\tilde{q}}/2$ and improves for heavier gluinos or heavier χ^0_1.

[255] ABREU 99G looked for events with an electron or neutrino and a jet in e^+e^- at 183 GeV. Squarks (or leptoquarks) could originate from a $LQ\overline{D}$ coupling of an electron with a quark from the fluctuation of a virtual photon. Limits on the couplings λ'_{1jk} as a function of the squark mass are shown in Fig. 4, assuming that only direct squark decays contribute.

[256] ABBOTT 98E searched in $\sim$ 115 pb^{-1} of $p\overline{p}$ collisions for events with $e\nu$+jets, originating from associated production of squarks followed by direct $\not{R}$ decay via $\lambda'_{1jk}L_1Q_jd^c_k$ couplings. Bounds are obtained by combining these results with the previous bound of ABBOTT 97B from the ee+jets channel and with a reinterpretation of ABACHI 96B $\nu\nu$+jets channel.

[257] ABE 98S looked in $\sim$ 110 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV for events with $\mu\mu$+jets originating from associated production of squarks followed by direct $\not{R}$ decay via $\lambda'_{2jk}L_2Q_jd^c_k$ couplings. Bounds are obtained on the production cross section times the square of the branching ratio, see Fig. 2. Mass limits result from the comparison with theoretical cross sections and branching ratio equal to 1 for $\tilde{u}_L$ and 1/2 for $\tilde{d}_R$.

[258] ACKERSTAFF 98V and ACCIARRI 98J studied the interference of t-channel squark ($\tilde{d}_R$) exchange via R-parity violating $\lambda'_{1jk}L_1Q_jd^c_k$ coupling in $e^+e^- \to q\overline{q}$. The limit is for λ'_{1jk}=0.3. See paper for related limits on $\tilde{u}_L$ exchange. Data collected at $\sqrt{s}$=130–172 GeV.

[259] BREITWEG 98 used positron+jet events with missing energy and momentum to look for $e^+q \to \tilde{e}\tilde{q}$ via gaugino-like neutralino exchange with decays into ($e\tilde{\chi}^0_1$)($q\tilde{\chi}^0_1$). See paper for dependences in $m_{\tilde{e}}$, $m_{\tilde{\chi}^0_1}$.

[260] DATTA 97 argues that the squark mass bound by ABACHI 95C can be weakened by 10–20 GeV if one relaxes the assumption of the universal scalar mass at the GUT-scale so that the $\tilde{\chi}^\pm_1$,$\tilde{\chi}^0_2$ in the squark cascade decays have dominant and invisible decays to $\tilde{\nu}$.

[261] DERRICK 97 looked for lepton-number violating final states via R-parity violating couplings $\lambda'_{ijk}L_iQ_jd_k$. When $\lambda'_{11k}\lambda'_{ijk} \neq 0$, the process $eu \to \tilde{d}^*_k \to \ell_iu_j$ is possible. When $\lambda'_{1j1}\lambda'_{ijk} \neq 0$, the process $e\overline{d} \to \tilde{u}^*_j \to \ell_i\overline{d}_k$ is possible. 100% branching fraction $\tilde{q} \to \ell j$ is assumed. The limit quoted here corresponds to $\tilde{t} \to \tau q$ decay, with λ'=0.3. For different channels, limits are slightly better. See Table 6 in their paper.

[262] HEWETT 97 reanalyzed the limits on possible resonances in di-jet mode ($\tilde{q} \to q\tilde{g}$) from ALITTI 93 quoted in "Limits for Excited q (q^*) from Single Production," ABE 96 in "SCALE LIMITS for Contact Interactions: $\Lambda(qqqq)$," and unpublished CDF, DØ bounds. The bound applies to the gluino mass of 5 GeV, and improves for lighter gluino. The analysis has gluinos in parton distribution function.

[263] TEREKHOV 97 improved the analysis of TEREKHOV 96 by including di-jet angular distributions in the analysis.

[264] AID 96C used positron+jet events with missing energy and momentum to look for $e^+q \to \tilde{e}\tilde{q}$ via neutralino exchange with decays into ($e\tilde{\chi}^0_1$)($q\tilde{\chi}^0_1$). See the paper for dependences on $m_{\tilde{e}}$, $m_{\tilde{\chi}^0_1}$.

[265] TEREKHOV 96 reanalyzed the limits on possible resonances in di-jet mode ($\tilde{u} \to u\tilde{g}$) from ABE 95N quoted in "MASS LIMITS for g_A (axigluon)." The bound applies only to the case with a light gluino.

[266] ABACHI 95C assume five degenerate squark flavors with $m_{\tilde{q}_L} = m_{\tilde{q}_R}$. Sleptons are assumed to be heavier than squarks. The limits are derived for fixed tanβ = 2.0 μ = $-$250 GeV, and m_{H^+}=500 GeV, and with the cascade decays of the squarks and gluinos calculated within the framework of the Minimal Supergravity scenario. The bounds are weakly sensitive to the three fixed parameters for a large fraction of parameter space. No limit is given for m_{gluino} >547 GeV.

[267] ABE 95T looked for a cascade decay of five degenerate squarks into $\tilde{\chi}^0_2$ which further decays into $\tilde{\chi}^0_1$ and a photon. No signal is observed. Limits vary widely depending on the choice of parameters. For $\mu = -40$ GeV, tanβ = 1.5, and heavy gluinos, the range 50<$m_{\tilde{q}}$ (GeV)<110 is excluded at 90% CL. See the paper for details.

[268] ABE 92L assume five degenerate squark flavors and $m_{\tilde{q}_L} = m_{\tilde{q}_R}$. ABE 92L includes the effect of cascade decay, for a particular choice of parameters, $\mu = -250$ GeV, tanβ = 2. Results are weakly sensitive to these parameters over much of parameter space. No limit for $m_{\tilde{q}} \leq 50$ GeV (but other experiments rule out that region). Limits are 10–20 GeV higher if B($\tilde{q} \to q\tilde{\gamma}$) = 1. Limit assumes GUT relations between gaugino masses and the gauge coupling; in particular that for $|\mu|$ not small, $m_{\tilde{\chi}^0_1} \approx m_{\tilde{g}}/6$. This last relation implies that as $m_{\tilde{g}}$ increases, the mass of $\tilde{\chi}^0_1$ will eventually exceed $m_{\tilde{q}}$ so that no decay is possible. Even before that occurs, the signal will disappear; in particular no bounds can be obtained for $m_{\tilde{g}}$ >410 GeV. m_{H^+}=500 GeV.

[269] ROY 92 reanalyzed CDF limits on di-lepton events to obtain limits on squark production in R-parity violating models. The 100% decay $\tilde{q} \to q\tilde{\chi}$ where $\tilde{\chi}$ is the LSP, and the LSP decays either into $\ell q\overline{d}$ or $\ell\ell\overline{e}$ is assumed.

[270] NOJIRI 91 argues that a heavy squark should be nearly degenerate with the gluino in minimal supergravity not to overclose the universe.

Long-lived $\tilde{q}$ (Squark) MASS LIMIT

The following are bounds on long-lived scalar quarks, assumed to hadronise into hadrons with lifetime long enough to escape the detector prior to a possible decay. Limits may depend on the mixing angle of mass eigenstates: $\tilde{q}_1 = \tilde{q}_L\cos\theta_q + \tilde{q}_R\sin\theta_q$.

The coupling to the Z^0 boson vanishes for up-type squarks when θ_u=0.98, and for down type squarks when θ_d=1.17.

[271] HEISTER 03H use e^+e^- data at and around the Z^0 peak to look for hadronizing stable squarks. Combining their results on searches for charged and neutral R-hadrons with JANOT 03, a lower limit of 15.7 GeV on the mass is obtained. Combining this further with the results of searches for tracks with anomalous ionization in data from 183 to 208 GeV yields the quoted bounds.

[272] ABREU 98P assumes that 40% of the squarks will hadronise into a charged hadron, and 60% into a neutral hadron which deposits most of its energy in hadron calorimeter. Data collected at $\sqrt{s}$=130–183 GeV.

$\tilde{b}$ (Sbottom) MASS LIMIT

Limits in e^+e^- depend on the mixing angle of the mass eigenstate $\tilde{b}_1 = \tilde{b}_L\cos\theta_b + \tilde{b}_R\sin\theta_b$. Coupling to the Z vanishes for $\theta_b \sim 1.17$. As a consequence, no absolute constraint in the mass region $\lesssim 40$ GeV is available in the literature at this time from e^+e^- collisions. In the Listings below, we use $\Delta m = m_{\tilde{b}_1} - m_{\tilde{\chi}^0_1}$.

[273] ACHARD 04 search for the production of $\tilde{b}\bar{\tilde{b}}$ in acoplanar b-tagged di-jet final states in the 192–209 GeV data. See Fig. 6 for the dependence of the limits on $m_{\tilde{\chi}^0_1}$. This limit supersedes ACCIARRI 99V.

[274] ABDALLAH 03M looked for $\tilde{b}$ pair production in events with acoplanar jets and $\not{E}$ at $\sqrt{s}$ = 189–208 GeV. The limit improves to 87 (98) GeV for all θ_b (θ_b = 0) for Δm > 10 GeV. See Fig. 24 and Table 11 for other choices of Δm. These limits include and update the results of ABREU,P 00D.

[275] ABBIENDI 02H search for events with two acoplanar jets and $\not{p}_T$ in the 161–209 GeV data. The limit assumes 100% branching ratio and uses the exclusion at large Δm from CDF (AFFOLDER 00D). For θ_b=0, the bound improves to > 96.9 GeV. See Fig. 4 and Table 6 for the more general dependence on the limits on Δm. These results supersede ABBIENDI 99M.

[276] HEISTER 02K search for bottom squarks in final states with acoplanar jets with b tagging, using 183–209 GeV data. The mass bound uses the CDF results from AFFOLDER 00D. See Fig. 5 for the more general dependence of the limits on Δm. Updates BARATE 01.

[277] SAVINOV 01 use data taken at $\sqrt{s}$=10.52 GeV, below the $B\overline{B}$ threshold. They look for events with a pair of leptons with opposite charge and a fully reconstructed hadronic D or D^* decay. These could originate from production of a light-sbottom hadron followed by $\tilde{B} \to D^{(*)}\ell^-\tilde{\nu}$, in case the $\tilde{\nu}$ is the LSP, or $\tilde{B} \to D^{(*)}\pi\ell^-$, in case of $\not{R}$. The mass range $3.5 \leq M(\tilde{B}) \leq 4.5$ GeV was explored, assuming 100% branching ratio for either of the decays. In the $\tilde{\nu}$ LSP scenario, the limit holds only for $M(\tilde{\nu})$ less than about 1 GeV and for the D^* decays it is reduced to the range 3.9–4.5 GeV. For the $\not{R}$ decay, the whole range is excluded.

[278] AFFOLDER 00D search for final states with 2 or 3 jets and $\not{E}_T$, one jet with a b tag. See their Fig. 3 for the mass exclusion in the $m_{\tilde{t}}$, $m_{\tilde{\chi}^0_1}$ plane.

[279] ABDALLAH 03C looked for events of the type $q\bar{q}R^{\pm}R^{\pm}$, $q\bar{q}R^{\pm}R^0$ or $q\bar{q}R^0R^0$ in e^+e^- interactions at $\sqrt{s} = 189 - 208$ GeV. The $R^{\pm}$ bound states are identified by anomalous dE/dx in the tracking chambers and the R^0 by missing energy due to their reduced energy loss in the calorimeters. Excluded mass regions in the $(m(\tilde{b}), m(\tilde{g}))$ plane for $m(\tilde{g}) > 2$ GeV are obtained for several values of the probability for the gluino to fragment into $R^{\pm}$ or R^0, as shown in their Fig. 19. The limit improves to 94 GeV for $\theta_b = 0$.

[280] BERGER 03 studies the constraints on a $\tilde{b}_1$ with mass in the 2.2–5.5 GeV region coming from radiative decays of Υ(nS) into sbottomonium. The constraints apply only if $\tilde{b}_1$ lives long enough to permit formation of the sbottomonium bound state. A small region of mass in the $m_{\tilde{b}_1} - m_{\tilde{g}}$ plane survives current experimental constraints from CLEO.

[281] HEISTER 03G searches for the production of $\tilde{b}$ pairs in the case of $\not{R}$ prompt decays with $LL\overline{E}$, $LQ\overline{D}$ or $\overline{UDD}$ couplings at $\sqrt{s}$ = 189–209 GeV. The limit holds for indirect decays mediated by $\not{R}$ $\overline{UDD}$ couplings. It improves to 90 GeV for indirect decays mediated by $\not{R}$ $LL\overline{E}$ couplings and to 80 GeV for indirect decays mediated by $\not{R}$ $LQ\overline{D}$ couplings. Supersedes the results from BARATE 01B.

[282] HEISTER 03H use their results on bounds on stable squarks, on stable gluinos and on squarks decaying to a stable gluino from the same paper to derive a mass limit on $\tilde{b}$, see their Fig. 13.

[283] ACHARD 02 searches for the production of squarks in the case of $\not{R}$ prompt decays with $\overline{UDD}$ couplings at $\sqrt{s}$=189–208 GeV. The search is performed for direct and indirect decays, assuming one coupling at the time to be nonzero. The limit is computed for the minimal cross section and holds for indirect decays and reaches 55 GeV for direct decays.

[284] BAEK 02 studies the constraints on a $\tilde{b}_1$ with mass in the 2.2–5.5 GeV region coming from precision measurements of Z^0 decays. It is noted that CP-violating couplings in the MSSM parameters relax the strong constraints otherwised derived from CP conservation.

[285] BECHER 02 studies the constraints on a $\tilde{b}_1$ with mass in the 2.2–5.5 GeV region coming from radiative B meson decays, and sets limits on the off-diagonal flavor-changing couplings $q\tilde{b}\tilde{g}$ (q=d,s).

[286] CHEUNG 02B studies the constraints on a $\tilde{b}_1$ with mass in the 2.2–5.5 GeV region and a gluino in the mass range 12–16 GeV, using precision measurements of Z^0 decays and e^+e^- annihilations at LEP2. Few detectable events are predicted in the LEP2 data for the model proposed by BERGER 01.

[287] CHO 02 studies the constraints on a $\tilde{b}_1$ with mass in the 2.2–5.5 GeV region coming from precision measurements of Z^0 decays. Strong constraints are obtained for CP-conserving MSSM couplings.

[288] ABREU 01D searches for multi-jet events, expected in the case of prompt decays from $\not{R}$ $\overline{UDD}$ couplings and indirect decays, using data from $\sqrt{s}$=189 GeV. Limits are obtained in the plane of the squark mass versus $m_{\tilde{\chi}^0_1}$. The mass limit is derived using the constraint on the neutralino mass from the same paper (see the section on unstable $\tilde{\chi}^0_1$). See Fig. 9 for other choices of Δm.

[289] BERGER 01 reanalyzed interpretation of Tevatron data on bottom-quark production. Argues that pair production of light gluinos ($m\sim$ 12–16 GeV) with subsequent 2-body decay into a light sbottom ($m\sim$ 2–5.5 GeV) and bottom can reconcile Tevatron data with predictions of perturbative QCD for the bottom production rate. The sbottom must either decay hadronically via a R-parity- and B-violating interaction, or be long-lived. Constraints on the mass spectrum are derived from the measurements of time-averaged B^0-$\overline{B}^0$ mixing.

[290] ABBOTT 99F looked for events with two jets, with or without an associated muon from b decay, and $\not{E}_T$. See Fig. 2 for the dependence of the limit on $m_{\tilde{\chi}^0_1}$. No limit for $m_{\tilde{\chi}^0_1} > 47$ GeV.

$\tilde{t}$ (Stop) MASS LIMIT

Limits depend on the decay mode. In e^+e^- collisions they also depend on the mixing angle of the mass eigenstate $\tilde{t}_1 = \tilde{t}_L\cos\theta_t + \tilde{t}_R\sin\theta_t$. The coupling to the Z vanishes when $\theta_t = 0.98$. In the Listings below, we use $\Delta m \equiv m_{\tilde{t}_1} - m_{\tilde{\chi}^0_1}$ or $\Delta m \equiv m_{\tilde{t}_1} - m_{\tilde{\nu}}$, depending on relevant decay mode. See also bounds in "$\tilde{q}$ (Squark) MASS LIMIT." Limits made obsolete by the most recent analyses of e^+e^- and $p\overline{p}$ collisions can be found in previous Editions of this *Review*.

[291] ACHARD 04 search in the 192–209 GeV data for the production of $\tilde{t}\bar{\tilde{t}}$ in acoplanar di-jet final states and, in case of $b\ell\tilde{\nu}$ ($b\tau\tilde{\nu}$) final states, two leptons (taus). The limits for θ_t=0 improve to 95, 96 and 93 GeV, respectively. All limits assume 100% branching ratio for the respective decay modes. See Fig. 6 for the dependence of the limits on $m_{\tilde{\chi}^0_1}$. These limits supersede ACCIARRI 99V.

[292] ABDALLAH 03M looked for $\tilde{t}$ pair production in events with acoplanar jets and $\not{E}$ at $\sqrt{s}$ = 189–208 GeV. See Fig. 23 and Table 11 for other choices of Δm. These limits include and update the results of ABREU,P 00D.

[293] ACOSTA 03C searched in 107 pb^{-1} of $p\bar{p}$ collisions at $\sqrt{s}$=1.8 TeV for pair production of $\tilde{t}$ followed by the decay $\tilde{t} \to b\ell\tilde{\nu}$. They looked for events with two isolated leptons (e or μ), at least one jet and $\not{E}_T$. The excluded mass range is reduced for larger $m_{\tilde{\nu}}$, and no limit is set for $m_{\tilde{\nu}} > 88.4$ GeV (see Fig. 2).

[294] ABAZOV 02C looked in 108.3pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV for events with $e\mu\not{E}_T$, originating from associated production $\tilde{t}\bar{\tilde{t}}$. Branching ratios are assumed to be 100%. The bound for the $b\ell\tilde{\nu}$ decay weakens for large $\tilde{\nu}$ mass (see Fig. 3), and no limit is set when $m_{\tilde{\nu}} > 85$ GeV. See Fig. 4 for the limits in case of decays to a real $\tilde{\chi}^{\pm}_1$, followed by $\tilde{\chi}^{\pm}_1 \to \ell\tilde{\nu}$, as a function of $m_{\tilde{\chi}^{\pm}_1}$.

[295] ABBIENDI 02H looked for events with two acoplanar jets, $\not{p}_T$, and, in the case of $b\ell\tilde{\nu}$ final states, two leptons, in the 161–209 GeV data. The bound for $c\tilde{\chi}^0_1$ applies to the region where $\Delta m < m_W + m_b$, else the decay $\tilde{t}_1 \to b\tilde{\chi}^0_1 W^+$ becomes dominant. The limit for $b\ell\tilde{\nu}$ assumes equal branching ratios for the three lepton flavors and for $b\tau\tilde{\nu}$ 100% for this channel. For θ_t=0, the bounds improve to > 97.6 GeV ($c\tilde{\chi}^0_1$), > 96.0 GeV ($b\ell\tilde{\nu}$), and > 95.5 ($b\tau\tilde{\nu}$). See Figs. 5–6 and Table 5 for the more general dependence of the limits on Δm. These results supersede ABBIENDI 99M.

[296] HEISTER 02K search for top squarks in final states with jets (with/without b tagging or leptons) or long-lived hadrons, using 183–209 GeV data. The absolute mass bound is obtained by varying the branching ratio of $\tilde{t} \to c\tilde{\chi}^0_1$ and the lepton fraction in $\tilde{t} \to b\tilde{\chi}^0_1 f\overline{f}'$ decays. The mass bound for $\tilde{t} \to c\tilde{\chi}^0_1$ uses the CDF results from AFFOLDER 00D and for $\tilde{t} \to b\ell\tilde{\nu}$ the DØ results from ABAZOV 02C. See Figs. 2–5 for the more general dependence of the limits on Δm. Updates BARATE 01 and BARATE 00P.

[297] ABDALLAH 03C looked for events of the type $q\bar{q}R^{\pm}R^{\pm}$, $q\bar{q}R^{\pm}R^0$ or $q\bar{q}R^0R^0$ in e^+e^- interactions at $\sqrt{s} = 189 - 208$ GeV. The $R^{\pm}$ bound states are identified by anomalous dE/dx in the tracking chambers and the R^0 by missing energy, due to their reduced energy loss in the calorimeters. Excluded mass regions in the $(m(\tilde{t}), m(\tilde{g}))$ plane for $m(\tilde{g}) > 2$ GeV are obtained for several values of the probability for the gluino to fragment into $R^{\pm}$ or R^0, as shown in their Fig. 18. The limit improves to 90 GeV for $\theta_t = 0$.

[298] Theoretical analysis of $e^+e^- + 2$ jet final states from the RPV decay of $\tilde{t}\bar{\tilde{t}}^*$ pairs produced in $p\overline{p}$ collisions at $\sqrt{S} = 1.8$ TeV. 95%CL limits of 220 (165) GeV are derived for $B(\tilde{t} \to eq)$=1 (0.5).

[299] HEISTER 03G searches for the production of $\tilde{t}$ pairs in the case of $\not{R}$ prompt decays with $LL\overline{E}$, $LQ\overline{D}$ or $\overline{UDD}$ couplings at $\sqrt{s} = 189–209$ GeV. The limit holds for indirect decays mediated by $\not{R}$ $\overline{UDD}$ couplings. It improves to 91 GeV for indirect decays mediated by $\not{R}$ $LL\overline{E}$ couplings, to 97 GeV for direct (assuming $B(\tilde{t}_L \to q\tau) = 100\%$) and to 85 GeV for indirect decays mediated by $\not{R}$ $LQ\overline{D}$ couplings. Supersedes the results from BARATE 01B.

[300] HEISTER 03H use e^+e^- data from 183–208 GeV to look for the production of stop decaying into a c quark and a stable gluino hadronizing into charged or neutral R-hadrons. Combining these results with bounds on stable squarks and on a stable gluino LSP from the same paper yields the quoted limit. See their Fig. 13 for the dependence of the mass limit on the gluino mass and on θ_t.

[301] ACHARD 02 searches for the production of squarks in the case of $\not{R}$ prompt decays with $\overline{UDD}$ couplings at $\sqrt{s}$=189–208 GeV. The search is performed for direct and indirect decays, assuming one coupling at the time to be nonzero. The limit is computed for the minimal cross section and holds for both direct and indirect decays.

[302] ABREU 01D searches for multi-jet events, expected in the case of prompt decays from $\not{R}$ $\overline{UDD}$ couplings and indirect decays, using data from $\sqrt{s}$=189 GeV. Limits are obtained in the plane of the squark mass versus $m_{\tilde{\chi}^0_1}$. The mass limit is derived using the constraint on the neutralino mass from the same paper (see the section on unstable $\tilde{\chi}^0_1$). See Fig. 9 for other choices of Δm.

[303] AFFOLDER 01B searches for decays of the top quark into stop and LSP, in $t\bar{t}$ events. Limits on the stop mass as a function of the LSP mass and of the decay branching ratio are shown in Fig. 3. They exclude branching ratios in excess of 45% for SLP masses up to 40 GeV.

[304] ABBIENDI 00 searches for the production of stop in the case of R-parity violation with $\overline{UDD}$ or $LQ\overline{D}$ couplings, using data from $\sqrt{s}$=183 GeV. They investigate topologies with multiple leptons, jets plus leptons, or multiple jets, assuming one coupling at the time to be non-zero. For mass exclusion limits relative to $LQ\overline{D}$-induced decays, see their Table 5.

[305] ABREU 00I searches for the production of stop in the case of R-parity violation with $LL\overline{E}$ couplings, for which only indirect decays are allowed. They investigate topologies with jets plus leptons in data from $\sqrt{s}$=183 GeV. The lower bound on the stop mass assumes a neutralino mass limit of 27 GeV, also derived in ABREU 00I.

[306] AFFOLDER 00D search for final states with 2 or 3 jets and $\not{E}_T$, one jet with a c tag. See their Fig. 2 for the mass exclusion in the $(m_{\tilde{t}}, m_{\tilde{\chi}^0_1})$ plane. The maximum excluded $m_{\tilde{t}}$ value is 119 GeV, for $m_{\tilde{\chi}^0_1}$= 40 GeV.

[307] AFFOLDER 00G searches for $\tilde{t}_1\bar{\tilde{t}}^*_1$ production, with $\tilde{t}_1 \to b\ell\tilde{\nu}$, leading to topologies with ≥ 1 isolated lepton (e or μ), $\not{E}_T$, and ≥ 2 jets with ≥ 1 tagged as b quark by a secondary vertex. See Fig. 4 for the excluded mass range as a function of $m_{\tilde{\nu}}$. Cross-section limits for $\tilde{t}_1\bar{\tilde{t}}^*_1$, with $\tilde{t}_1 \to b\chi^{\pm}_1$ ($\chi^{\pm}_1 \to \ell^{\pm}\nu\tilde{\chi}^0_1$), are given in Fig. 2.

[308] BARATE 00P use data from $\sqrt{s}$= 189–202 GeV to explore the region of small mass difference between the stop and the neutralino by searching heavy stable charged particles or tracks with large impact parameters. For prompt decays, they make use of acoplanar jets from BARATE 99Q, updated up to 202 GeV. The limit is reached for Δm=1.6 GeV and a decay length of 1 cm. If the MSSM relation between the decay width and Δm is used, the limit improves to 63 GeV. It is set for Δm=1.9 GeV. tanβ=2.6, and $\theta_{\tilde{t}}$=0.98, and large negative μ.

[309] ABE 99M looked in 107 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV for events with like sign dielectrons and two or more jets from the sequential decays $\tilde{q} \to q\tilde{\chi}^0_1$ and $\tilde{\chi}^0_1 \to eq\overline{q}'$, assuming $\not{R}$ coupling $L_1 Q_j D^c_k$, with j=2,3 and k=1,2,3. They assume $B(\tilde{t}_1 \to c\tilde{\chi}^0_1)$=1, $B(\tilde{\chi}^0_1 \to eq\overline{q}')$=0.25 for both e^+ and e^-, and $m_{\tilde{\chi}^0_1} \geq m_{\tilde{t}_1}/2$. The limit improves for heavier $\tilde{\chi}^0_1$.

[310] ABACHI 96B searches for final states with 2 jets and missing E_T. Limits on $m_{\tilde{t}}$ are given as a function of $m_{\tilde{\chi}^0_1}$. See Fig. 4 for details.

[311] AID 96 considers photoproduction of $\tilde{t}\bar{\tilde{t}}$ pairs, with 100% R-parity violating decays of $\tilde{t}$ to eq, with q=d, s, or b quarks.

[312] AID 96 considers production and decay of $\tilde{t}$ via the R-parity violating coupling $\lambda' L_1 Q_3 d^c_1$.

[313] CHO 96 studied the consistency among the B^0-$\overline{B}^0$ mixing, ϵ in K^0-$\overline{K}^0$ mixing, and the measurements of V_{cb}, V_{ub}/V_{cb}. For the range 25.5 GeV$< m_{\tilde{t}_1} <$ $m_Z/2$ left by AKERS 94K for $\theta_t = 0.98$, and within the allowed range in M_2-μ parameter space from chargino, neutralino searches by ACCIARRI 95E, they found the scalar top contribution to B^0-$\overline{B}^0$ mixing and ϵ to be too large if tanβ <2. For more on their assumptions, see the paper and their reference 10.

[314] BUSKULIC 95E looked for $Z \to \tilde{t}\bar{\tilde{t}}$, where $\tilde{t} \to c\chi^0_1$ and χ^0_1 decays via R-parity violating interactions into two leptons and a neutrino.

[315] SHIRAI 94 bound assumes the cross section without the s-channel Z-exchange and the QCD correction, underestimating the cross section up to 20% and 30%, respectively. They assume m_c=1.5 GeV.

Heavy $\tilde{g}$ (Gluino) MASS LIMIT

For $m_{\tilde{g}} > 60–70$ GeV, it is expected that gluinos would undergo a cascade decay via a number of neutralinos and/or charginos rather than undergo a direct decay to photinos as assumed by some papers. Limits obtained when direct decay is assumed are usually higher than limits when cascade decays are included. Limits made obsolete by the most recent analyses of $p\overline{p}$ collisions can be found in previous Editions of this *Review*.

[316] AFFOLDER 02 searched in ~ 84 pb^{-1} of $p\overline{p}$ collisions for events with ≥ 3 jets and $\not{E}_T$, arising from the production of gluinos and/or squarks. Limits are derived by scanning the parameter space, for $m_{\tilde{q}} \geq m_{\tilde{g}}$ in the framework of minimal Supergravity, assuming five flavors of degenerate squarks, and for $m_{\tilde{g}} < m_{\tilde{g}}$ in the framework of constrained MSSM, assuming conservatively four flavors of degenerate squarks. See Fig. 3 for the variation of the limit as function of the squark mass. Supersedes the results of ABE 97K.

[317] ABBOTT 01D looked in ~ 108 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV for events with ee, $\mu\mu$, or $e\mu$ accompanied by at least 2 jets and $\not{E}_T$. Excluded regions are obtained in the MSUGRA framework from a scan over the parameters $0 < m_0 < 300$ GeV, $10 < m_{1/2} < 110$ GeV, and $1.2 <$ tanβ <10.

[318] AFFOLDER 01J searched in ~ 106 pb^{-1} of $p\overline{p}$ collisions for events with 2 like-sign leptons (e or μ), ≥ 2 jets and $\not{E}_T$, expected to arise from the production of gluinos and/or squarks with cascade decays into $\tilde{\chi}^{\pm}$ or $\tilde{\chi}^0_2$. Spectra and decay rates are evaluated

in the framework of minimal Supergravity, assuming five flavors of degenerate squarks and a pseudoscalar Higgs mass m_A=500 GeV. The limits are derived for tanβ=2, μ=−800 GeV, and scanning over $m_{\tilde{g}}$ and $m_{\tilde{q}}$. See Fig. 2 for the variation of the limit as function of the squark mass. These limits supersede the results of ABE 96D.

[319] ABBOTT 99L consider events with three or more jets and large $\not{E}_T$. Spectra and decay rates are evaluated in the framework of minimal Supergravity, assuming five flavors of degenerate squarks, and scanning the space of the universal gaugino ($m_{1/2}$) and scalar (m_0) masses See their Figs. 2–3 for the dependence of the limit on the relative value of $m_{\tilde{q}}$ and $m_{\tilde{g}}$.

[320] ABAZOV 02F looked in 77.5 pb^{-1} of $p\overline{p}$ collisions at 1.8 TeV for events with $\geq 2\mu + \geq$ 4jets, originating from associated production of squarks followed by an indirect $\not{R}$ decay (of the $\tilde{\chi}_1^0$) via $L\overline{Q}D$ couplings of the type λ'_{2jk} where j=1,2 and k=1,2,3. Bounds are obtained in the MSUGRA scenario by a scan in the range $0 \leq M_0 \leq 400$ GeV, $60 \leq m_{1/2} \leq 120$ GeV for fixed values A_0=0, $\mu < 0$, and tanβ=2 or 6. The bounds are weaker for tanβ=6. See Figs. 2,3 for the exclusion contours in $m_{1/2}$ versus m_0 for tanβ=2 and 6, respectively.

[321] ABAZOV 02G search for associated production of gluinos and squarks in 92.7 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV, using events with one electron, $\geq$ 4 jets, and large $\not{E}_T$. The results are compared to a MSUGRA scenario with $\mu < 0$, A_0=0, and tanβ=3 and allow to exclude a region of the (m_0,$m_{1/2}$) shown in Fig. 11.

[322] CHEUNG 02B studies the constraints on a $\tilde{b}_1$ with mass in the 2.2–5.5 GeV region and a gluino in the mass range 12–16 GeV, using precision measurements of Z^0 decays and e^+e^- annihilations at LEP2. Few detectable events are predicted in the LEP2 data for the model proposed by BERGER 01.

[323] BERGER 01 reanalyzed interpretation of Tevatron data on bottom-quark production. Argues that pair production of light gluinos ($m\sim$ 12–16 GeV) with subsequent 2-body decay into a light sbottom ($m\sim$ 2–5.5 GeV) and bottom can reconcile Tevatron data with predictions of perturbative QCD for the bottom production rate. The sbottom must either decay hadronically via a R-parity- and B-violating interaction, or be long-lived.

[324] ABBOTT 99 searched for $\gamma\not{E}_T + \geq 2$ jet final states, and set limits on $\sigma(p\overline{p} \to \tilde{g}+X)\cdot B(\tilde{g} \to \gamma\not{E}_T X)$. The quoted limits correspond to $m_{\tilde{q}} \geq m_{\tilde{g}}$, with B($\tilde{\chi}_2^0 \to \tilde{\chi}_1^0\gamma$)=1 and B($\tilde{\chi}_1^0 \to \tilde{G}\gamma$)=1, respectively. They improve to 310 GeV (360 GeV in the case of $\gamma\tilde{G}$ decay) for $m_{\tilde{g}}$=$m_{\tilde{q}}$.

[325] ABBOTT 99K uses events with an electron pair and four jets to search for the decay of the $\tilde{\chi}_1^0$ LSP via $\not{R}$ $L\overline{Q}D$ couplings. The particle spectrum and decay branching ratios are taken in the framework of minimal supergravity. An excluded region at 95% CL is obtained in the (m_0,$m_{1/2}$) plane under the assumption that A_0=0, $\mu < 0$, tanβ=2 and any one of the couplings $\lambda'_{1jk} > 10^{-3}$ (j=1,2 and k=1,2,3) and from which the above limit is computed. For equal mass squarks and gluinos, the corresponding limit is 277 GeV. The results are essentially independent of A_0, but the limit deteriorates rapidly with increasing tanβ or $\mu > 0$.

[326] ABACHI 95C assume five degenerate squark flavors with with $m_{\tilde{q}_L} = m_{\tilde{q}_R}$. Sleptons are assumed to be heavier than squarks. The limits are derived for fixed tanβ = 2.0 μ = −250 GeV, and m_{H^+}=500 GeV, and with the cascade decays of the squarks and gluinos calculated within the framework of the Minimal Supergravity scenario. The bounds are weakly sensitive to the three fixed parameters for a large fraction of parameter space.

[327] ABE 95T looked for a cascade decay of gluino into $\tilde{\chi}_2^0$ which further decays into $\tilde{\chi}_1^0$ and a photon. No signal is observed. Limits vary widely depending on the choice of parameters. For μ = −40 GeV, tanβ = 1.5, and heavy squarks, the range 50<$m_{\tilde{g}}$ (GeV)<140 is excluded at 90% CL. See the paper for details.

[328] HEBBEKER 93 combined jet analyses at various e^+e^- colliders. The 4-jet analyses at TRISTAN/LEP and the measured α_s at PEP/PETRA/TRISTAN/LEP are used. A constraint on effective number of quarks N=6.3 ± 1.1 is obtained, which is compared to that with a light gluino, N=8.

[329] ABE 92L bounds are based on similar assumptions as ABACHI 95C. Not sensitive to m_{gluino} <40 GeV (but other experiments rule out that region).

[330] ROY 92 reanalyzed CDF limits on di-lepton events to obtain limits on gluino production in R-parity violating models. The 100% decay $\tilde{g} \to q\overline{q}\tilde{\chi}$ where $\tilde{\chi}$ is the LSP, and the LSP decays either into $\ell q\overline{d}$ or $\ell\ell\overline{e}$ is assumed.

[331] NOJIRI 91 argues that a heavy gluino should be nearly degenerate with squarks in minimal supergravity not to overclose the universe.

[332] The limits of ALBAJAR 87D are from $p\overline{p} \to \tilde{g}\tilde{g}X$ ($\tilde{g} \to q\overline{q}\tilde{\gamma}$) and assume $m_{\tilde{q}} > m_{\tilde{g}}$. These limits apply for $m_{\tilde{\gamma}} \lesssim$ 20 GeV and $\tau(\tilde{g}) < 10^{-10}$ s.

[333] The limit of ANSARI 87D assumes $m_{\tilde{q}} > m_{\tilde{g}}$ and $m_{\tilde{\gamma}} \approx 0$.

Long-lived/light $\tilde{g}$ (Gluino) MASS LIMIT

Limits on light gluinos ($m_{\tilde{g}} < 5$ GeV), or gluinos which leave the detector before decaying.

[334] ABDALLAH 03C looked for events of the type $q\bar{q}R^{\pm}R^{\pm}$, $q\bar{q}R^{\pm}R^0$ or $q\bar{q}R^0R^0$ in e^+e^- interactions at 91.2 GeV collected in 1994. The $R^{\pm}$ bound states are identified by anomalous dE/dx in the tracking chambers and the R^0 by missing energy, due to their reduced energy loss in the calorimeters. The upper value of the excluded range depends on the probability for the gluino to fragment into $R^{\pm}$ or R^0, see their Fig. 17. It improves to 23 GeV for 100% fragmentation to $R^{\pm}$.

[335] ABDALLAH 03G used e^+e^- data at and around the Z^0 peak, above the Z^0 up to $\sqrt{s}$ = 202 GeV and events from radiative return to cover the low energy region. They perform a direct measurement of the QCD beta-function from the means of fully inclusive event observables. Compared to the energy range, gluinos below 5 GeV can be considered massless and are firmly excluded by the measurement.

[336] HEISTER 03 use e^+e^- data from 1994 and 1995 at and around the Z^0 peak to measure the 4-jet rate and angular correlations. The comparison with QCD NLO calculations allow $\alpha_S(M_Z)$ and the color factor ratios to be extracted and the results are in agreement with the expectations from QCD. The inclusion of a massless gluino in the beta functions yields $T_R/C_F = 0.15 \pm 0.06 \pm 0.06$ (expectation is $T_R/C_F = 3/8$), excluding a massless gluino at more than 95% CL. As no NLO calculations are available for massive gluinos, the earlier LO results from BARATE 97L for massive gluinos remain valid.

[337] HEISTER 03H use e^+e^- data at and around the Z^0 peak to look for stable gluinos hadronizing into charged or neutral R-hadrons with arbitrary branching ratios. Combining these results with bounds on the Z^0 hadronic width from electroweak measurements (JANOT 03) to cover the low mass region the quoted lower limit on the mass of a long-lived gluino is obtained.

[338] JANOT 03 excludes a light gluino from the upper limit on an additional contribution to the Z hadronic width. At higher confidence levels, $m_{\tilde{g}} > 5.3(4.2)$ GeV at $3\sigma(5\sigma)$ level.

[339] MAFI 00 reanalyzed CDF data assuming a stable heavy gluino as the LSP, with model for R-hadron-nucleon scattering. Gluino masses between 35 GeV and 115 GeV are excluded based on the CDF Run I data. Combined with the analysis of BAER 99, this allows a LSP gluino mass between 25 and 35 GeV if the probability of fragmentation into charged R-hadron P>1/2. The cosmological exclusion of such a gluino LSP are assumed to be avoided as in BAER 99. Gluino could be NLSP with $\tau_{\tilde{g}} \sim 100$ yrs, and decay to gluon gravitino.

[340] ALAVI-HARATI 99E looked for R^0 bound states, yielding $\pi^+\pi^-$ or π^0 in the final state. The experiment is sensitive to values of $\Delta m = m_{R^0} - m_{\tilde{\gamma}}$ larger than 280 MeV and 140 MeV for the two decay modes, respectively, and to R^0 mass and lifetime in the ranges 0.8–5 GeV and 10^{-10}–10^{-3} s. The limits obtained depend on B($R^0 \to \pi^+\pi^-$photino) and B($R^0 \to \pi^0$photino) on the value of $m_{R^0}/m_{\tilde{\gamma}}$, and on the ratio of production rates $\sigma(R^0)/\sigma(K_L^0)$. See Figures in the paper for the excluded R^0 production rates as a function of Δm, R^0 mass and lifetime. Using the production rates expected from perturbative QCD, and assuming dominance of the above decay channels over the suitable phase space, R^0 masses in the range 0.8–5 GeV are excluded at 90%CL for a large fraction of the sensitive lifetime region. ALAVI-HARATI 99E updates and supersedes the results of ADAMS 97B.

[341] BAER 99 set constraints on the existence of stable $\tilde{g}$ hadrons, in the mass range $m_{\tilde{g}} > 3$ GeV. They argue that strong-interaction effects in the low-energy annihilation rates could leave small enough relic densities to evade cosmological constraints up to $m_{\tilde{g}} < 10$ TeV. They consider jet+$\not{E}_T$ as well as heavy-ionizing charged-particle signatures from production of stable $\tilde{g}$ hadrons at LEP and Tevatron, developing modes for the energy loss of $\tilde{g}$ hadrons inside the detectors. Results are obtained as a function of the fragmentation probability P of the $\tilde{g}$ into a charged hadron. For P< 1/2, and for various energy-loss models, OPAL and CDF data exclude gluinos in the 3 <$m_{\tilde{g}}$(GeV)< 130 mass range. For P> 1/2, gluinos are excluded in the mass ranges 3 <$m_{\tilde{g}}$(GeV)< 23 and 50 <$m_{\tilde{g}}$(GeV)< 200.

[342] FANTI 99 looked for R^0 bound states yielding high P_T $\eta \rightarrow 3\pi^0$ decays. The experiment is sensitive to a region of R^0 mass and lifetime in the ranges of 1–5 GeV and 10^{-10}–10^{-3} s. The limits obtained depend on B($R^0 \rightarrow \eta\tilde{\gamma}$), on the value of $m_{R^0}/m_{\tilde{\gamma}}$, and on the ratio of production rates $\sigma(R^0)/\sigma(K^0_L)$. See Fig. 6–7 for the excluded production rates as a function of R^0 mass and lifetime.

[343] ACKERSTAFF 98V excludes the light gluino with universal gaugino mass where charginos, neutralinos decay as $\tilde{\chi}^{\pm}_1, \tilde{\chi}^0_2 \rightarrow q\overline{q}\tilde{g}$ from total hadronic cross sections at $\sqrt{s}$=130–172 GeV. See paper for the case of nonuniversal gaugino mass.

[344] ADAMS 97B looked for $\rho^0 \rightarrow \pi^+\pi^-$ as a signature of R^0=($\tilde{g}g$) bound states. The experiment is sensitive to an R^0 mass range of 1.2–4.5 GeV and to a lifetime range of 10^{-10}–10^{-3} sec. Precise limits depend on the assumed value of $m_{R^0}/m_{\tilde{\gamma}}$. See Fig. 7 for the excluded mass and lifetime region.

[345] ALBUQUERQUE 97 looked for weakly decaying baryon-like states which contain a light gluino, following the suggestions in FARRAR 96. See their Table 1 for limits on the production fraction. These limits exclude gluino masses in the range 100–600 MeV for the predicted lifetimes (FARRAR 96) and production rates, which are assumed to be comparable to those of strange or charmed baryons.

[346] BARATE 97L studied the QCD color factors from four-jet angular correlations and the differential two-jet rate in Z decay. Limit obtained from the determination of n_f = 4.24 ± 0.29 ± 1.15, assuming T_F/C_F=3/8 and C_A/C_F=9/4.

[347] CSIKOR 97 combined the α_s from $\sigma(e^+e^- \rightarrow$ hadron), τ decay, and jet analysis in Z decay. They exclude a light gluino below 5 GeV at more than 99.7%CL.

[348] DEGOUVEA 97 reanalyzed AKERS 95A data on Z decay into four jets to place constraints on a light stable gluino. The mass limit corresponds to the pole mass of 2.8 GeV. The analysis, however, is limited to the leading-order QCD calculation.

[349] FARRAR 96 studied the possible R^0=($\tilde{g}g$) component in Fermilab E799 experiment and used its bound B($K^0_L \rightarrow \pi^0\nu\overline{\nu}$) $\leq 5.8\times10^{-5}$ to place constraints on the combination of R^0 production cross section and its lifetime.

[350] AKERS 95R looked for Z decay into $q\overline{q}\tilde{g}\tilde{g}$, by searching for charged particles with dE/dx consistent with $\tilde{g}$ fragmentation into a state $(\tilde{g}q\overline{q})^{\pm}$ with lifetime $\tau > 10^{-7}$ sec. The fragmentation probability into a charged state is assumed to be 25%.

[351] CLAVELLI 95 updates the analysis of CLAVELLI 93, based on a comparison of the hadronic widths of charmonium and bottomonium S-wave states. The analysis includes a parametrization of relativisitic corrections. Claims that the presence of a light gluino improves agreement with the data by slowing down the running of α_s.

[352] CAKIR 94 reanalyzed TUTS 87 and later unpublished data from CUSB to exclude pseudo-scalar gluinonium $\eta_{\tilde{g}}(\tilde{g}\tilde{g})$ of mass below 7 GeV. it was argued, however, that the perturbative QCD calculation of the branching fraction $\Upsilon \rightarrow \eta_{\tilde{g}}\gamma$ is unreliable for $m_{\eta_{\tilde{g}}} < 3$ GeV. The gluino mass is defined by $m_{\tilde{g}}$=($m_{\eta_{\tilde{q}}}$)/2. The limit holds for any gluino lifetime.

[353] LOPEZ 93C uses combined restraint from the radiative symmetry breaking scenario within the minimal supergravity model, and the LEP bounds on the (M_2,μ) plane. Claims that the light gluino window is strongly disfavored.

[354] CLAVELLI 92 claims that a light gluino mass around 4 GeV should exist to explain the discrepancy between α_s at LEP and at quarkonia (Υ), since a light gluino slows the running of the QCD coupling.

[355] ANTONIADIS 91 argue that possible light gluinos (< 5 GeV) contradict the observed running of α_s between 5 GeV and m_Z. The significance is less than 2 s.d.

[356] ANTONIADIS 91 interpret the search for missing energy events in 450 GeV/c pN collisions, AKESSON 91, in terms of light gluinos.

[357] NAKAMURA 89 searched for a long-lived ($\tau \gtrsim 10^{-7}$ s) charge-(±2) particle with mass $\lesssim$ 1.6 GeV in proton-Pt interactions at 12 GeV and found that the yield is less than 10^{-8} times that of the pion. This excludes R-Δ^{++} (a $\tilde{g}uuu$ state) lighter than 1.6 GeV.

[358] The limits assume $m_{\tilde{q}} = 100$ GeV. See their figure 3 for limits vs. $m_{\tilde{\gamma}}$.

[359] The gluino mass is defined by half the bound $\tilde{g}\tilde{g}$ mass. If zero gluino mass gives a $\tilde{g}\tilde{g}$ of mass about 1 GeV as suggested by various glueball mass estimates, then the low-mass bound can be replaced by zero. The high-mass bound is obtained by comparing the data with nonrelativistic potential-model estimates.

[360] ALBRECHT 86C search for secondary decay vertices from $\chi_{b1}(1P) \rightarrow \tilde{g}\tilde{g}g$ where $\tilde{g}$'s make long-lived hadrons. See their figure 4 for excluded region in the $m_{\tilde{g}} - m_{\tilde{q}}$ and $m_{\tilde{g}} - m_{\tilde{q}}$ plane. The lower $m_{\tilde{g}}$ region below ~ 2 GeV may be sensitive to fragmentation effects. Remark that the $\tilde{g}$-hadron mass is expected to be ~ 1 GeV (glueball mass) in the zero $\tilde{g}$ mass limit.

[361] BADIER 86 looked for secondary decay vertices from long-lived $\tilde{g}$-hadrons produced at 300 GeV π^- beam dump. The quoted bound assumes $\tilde{g}$-hadron nucleon total cross section of 10 μb. See their figure 7 for excluded region in the $m_{\tilde{g}} - m_{\tilde{q}}$ plane for several assumed total cross-section values.

[362] BARNETT 86 rule out light gluinos (m = 3–5 GeV) by calculating the monojet rate from gluino gluino gluon events (and from gluino gluino events) and by using UA1 data from $p\overline{p}$ collisions at CERN.

[363] VOLOSHIN 86 rules out stable gluino based on the cosmological argument that predicts too much hydrogen consisting of the charged stable hadron $\tilde{g}uud$. Quasi-stable ($\tau > 1.\times10^{-7}$ s) light gluino of $m_{\tilde{g}} < 3$ GeV is also ruled out by nonobservation of the stable charged particles, $\tilde{g}uud$, in high energy hadron collisions.

[364] COOPER-SARKAR 85B is BEBC beam-dump. Gluinos decaying in dump would yield $\tilde{\gamma}$'s in the detector giving neutral-current-like interactions. For $m_{\tilde{q}} >$330 GeV, no limit is set.

[365] DAWSON 85 first limit from neutral particle search. Second limit based on FNAL beam dump experiment.

[366] FARRAR 85 points out that BALL 84 analysis applies only if the $\tilde{g}$'s decay before interacting, i.e. $m_{\tilde{q}} < 80 m_{\tilde{g}}^{1.5}$. FARRAR 85 finds $m_{\tilde{g}} < 0.5$ not excluded for $m_{\tilde{q}}$ = 30–1000 GeV and $m_{\tilde{g}} < 1.0$ not excluded for $m_{\tilde{q}}$ = 100–500 GeV by BALL 84 experiment.

[367] GOLDMAN 85 use nonobservation of a pseudoscalar $\tilde{g}$-$\tilde{g}$ bound state in radiative ψ decay.

[368] HABER 85 is based on survey of all previous searches sensitive to low mass $\tilde{g}$'s. Limit makes assumptions regarding the lifetime and electric charge of the lightest supersymmetric particle.

[369] BALL 84 is FNAL beam dump experiment. Observed no interactions of $\tilde{\gamma}$ in the calorimeter, where $\tilde{\gamma}$'s are expected to come from pair-produced $\tilde{g}$'s. Search for long-lived $\tilde{\gamma}$ interacting in calorimeter 56m from target. Limit is for $m_{\tilde{q}}$ = 40 GeV and production cross section proportional to $A^{0.72}$. BALL 84 find no $\tilde{g}$ allowed below 4.1 GeV at CL = 90%. Their figure 1 shows dependence on $m_{\tilde{q}}$ and A. See also KANE 82.

[370] BRICK 84 reanalyzed FNAL 147 GeV HBC data for R-$\Delta(1232)^{++}$ with $\tau > 10^{-9}$ s and $p_{\rm lab} >$2 GeV. Set CL = 90% upper limits 6.1, 4.4, and 29 microbarns in pp, π^+p, K^+p collisions respectively. R-Δ^{++} is defined as being $\tilde{g}$ and 3 up quarks. If mass = 1.2–1.5 GeV, then limits may be lower than theory predictions.

[371] FARRAR 84 argues that $m_{\tilde{g}} <$100 MeV is not ruled out if the lightest R-hadrons are long-lived. A long lifetime would occur if R-hadrons are lighter than $\tilde{\gamma}$'s or if $m_{\tilde{q}} >$100 GeV.

[372] BERGSMA 83C is reanalysis of CERN-SPS beam-dump data. See their figure 1.

[373] CHANOWITZ 83 find in bag-model that charged s-hadron exists which is stable against strong decay if $m_{\tilde{g}} <$1 GeV. This is important since tracks from decay of neutral s-hadron cannot be reconstructed to primary vertex because of missed $\tilde{\gamma}$. Charged s-hadron leaves track from vertex.

[374] KANE 82 inferred above $\tilde{g}$ mass limit from retroactive analysis of hadronic collision and beam dump experiments. Limits valid if $\tilde{g}$ decays inside detector.

LIGHT $\tilde{G}$ (Gravitino) MASS LIMITS FROM COLLIDER EXPERIMENTS

The following are bounds on light ($\ll$ 1 eV) gravitino indirectly inferred from its coupling to matter suppressed by the gravitino decay constant.

Unless otherwise stated, all limits assume that other supersymmetric particles besides the gravitino are too heavy to be produced. The gravitino is assumed to be undetected and to give rise to a missing energy ($\not{E}$) signature.

[375] HEISTER 03C use the data from $\sqrt{s}$= 189-209 GeV to search for $\gamma\not{E}_T$ final states.

[376] ACOSTA 02H looked in 87 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV for events with a high-E_t photon and $\not{E}_T$. They compared the data with a GMSB model where the final state could arise from $q\overline{q} \rightarrow \tilde{G}\tilde{G}\gamma$. Since the cross section for this process scales as $1/|F|^4$, a limit at 95% CL is derived on $|F|^{1/2} > 221$ GeV. A model independent limit for the above topology is also given in the paper.

[377] ABBIENDI,G 00D searches for $\gamma\not{E}$ final states from $\sqrt{s}$=189 GeV.

[378] ABREU 00Z, ACCIARRI 99R search for $\gamma\not{E}$ final states using data from $\sqrt{s}$=189 GeV.

[379] AFFOLDER 00J searches for final states with an energetic jet (from quark or gluon) and large $\not{E}_T$ from undetected gravitinos.

[380] Searches for $\gamma\not{E}$ final states at $\sqrt{s}$=183 GeV.

Supersymmetry Miscellaneous Results

Results that do not appear under other headings or that make nonminimal assumptions.

VALUE	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
	[381] AFFOLDER	02D CDF		$p\overline{p} \rightarrow \gamma b\,(\not{E}_T)$
	[382] AFFOLDER	01H CDF		$p\overline{p} \rightarrow \gamma\gamma X$
	[383] ABBOTT	00G D0		$p\overline{p} \rightarrow 3\ell + \not{E}_T$, R, $LL\overline{E}$
	[384] ABREU,P	00C DLPH		$e^+e^- \rightarrow \gamma + S/P$
	[385] ABACHI	97 D0		$\gamma\gamma X$
	[386] BARBER	84B RVUE		
	[387] HOFFMAN	83 CNTR		$\pi p \rightarrow n(e^+e^-)$

[381] AFFOLDER 02D looked in 85 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV for events with a high-E_T photon, and a b-tagged jet with or without $\not{E}_T$. They compared the data with models where the final state could arise from cascade decays of gluinos and/or squarks into $\tilde{\chi}^{\pm}$ and $\tilde{\chi}^0_2$ or direct associated production of $\tilde{\chi}^0_2\tilde{\chi}^{\pm}_2$, followed by $\tilde{\chi}^0_2 \rightarrow \gamma\tilde{\chi}^0_1$ or a GMSB model where $\tilde{\chi}^0_1 \rightarrow \gamma\tilde{G}$. It is concluded that the experimental sensitivity is insufficient to detect the associated production or the GMSB model, but some sensitivity may exist to the cascade decays. A model independent limit for the above topology is also given in the paper.

[382] AFFOLDER 01H searches for $p\overline{p} \rightarrow \gamma\gamma X$ events, where the di-photon system originates from sgoldstino production, in 100 pb^{-1} of data. Upper limits on the cross section times branching ratio are shown as function of the di-photon mass >70 GeV in Fig. 5. Excluded regions are derived in the plane of the sgoldstino mass versus the supersymmetry breaking scale for two representative sets of parameter values, as shown in Figs. 6 and 7.

[383] ABBOTT 00G searches for trilepton final states (ℓ=e,μ) with $\not{E}_T$ from the indirect decay of gaugino via $LL\overline{E}$ couplings. Efficiencies are computed for all possible production and decay modes of SUSY particles in the framework of the Minimal Supergravity scenario. See Figs. 1–4 for excluded regions in the $m_{1/2}$ versus m_0 plane.

[384] ABREU,P 00C look for the CP-even (S) and CP-odd (P) scalar partners of the goldstino, expected to be produced in association with a photon. The S/P decay into two photons or into two gluons and both the tri-photon and the photon + two jets topologies are investigated. Upper limits on the production cross section are shown in Fig. 5 and the excluded regions in Fig. 6. Data collected at $\sqrt{s}$= 189–202 GeV.

[385] ABACHI 97 searched for $p\overline{p} \rightarrow \gamma\gamma\not{E}_T + X$ as supersymmetry signature. It can be caused by selectron, sneutrino, or neutralino production with a radiative decay of their decay products. They placed limits on cross sections.

[386] BARBER 84B consider that $\tilde{\mu}$ and $\tilde{e}$ may mix leading to $\mu \rightarrow e\tilde{\gamma}\tilde{\gamma}$. They discuss mass-mixing limits from decay dist. asym. in LBL-TRIUMF data and e^+ polarization in SIN data.

[387] HOFFMAN 83 set CL = 90% limit $d\sigma/dt$ B(e^+e^-) $< 3.5 \times 10^{-32}$ cm^2/GeV^2 for spin-1 partner of Goldstone fermions with $140 < m < 160$ MeV decaying $\rightarrow e^+e^-$ pair.

Technicolor

DYNAMICAL ELECTROWEAK SYMMETRY BREAKING

Revised August 2003 by R.S. Chivukula and M. Narain (Boston University) and J. Womersley (Fermilab).

In theories of dynamical electroweak symmetry breaking, the electroweak interactions are broken to electromagnetism by the vacuum expectation value of a fermion bilinear. These theories may thereby avoid the introduction of fundamental scalar particles, of which we have no examples in nature. In this note, we review the status of experimental searches for the particles predicted in technicolor, topcolor, and related models. The limits from these searches are summarized in Table 1.

I. Technicolor

The earliest models [1,2] of dynamical electroweak symmetry breaking [3] include a new non-abelian gauge theory ("technicolor") and additional massless fermions ("technifermions") which feel this new force. The global chiral symmetry of the fermions is spontaneously broken by the formation of a technifermion condensate, just as the approximate chiral SU(2) $\times$ $SU(2)$ symmetry in QCD is broken down to SU(2) isospin by the formation of a quark condensate. If the quantum numbers of the technifermions are chosen correctly (*e.g.* by choosing technifermions in the fundamental representation of an SU(N) technicolor gauge group, with the left-handed technifermions being weak doublets and the right-handed ones weak singlets) this condensate can break the electroweak interactions down to electromagnetism.

The breaking of the global chiral symmetries implies the existence of Goldstone bosons, the "technipions" (π_T). Through the Higgs mechanism, three of the Goldstone bosons become the longitudinal components of the W and Z, and the weak gauge bosons acquire a mass proportional to the technipion decay constant (the analog of f_π in QCD). The quantum numbers and masses of any remaining technipions are model dependent. There may be technipions which are colored (octets and triplets) as well as those carrying electroweak quantum numbers, and some color-singlet technipions are too light [4,5] unless additional sources of chiral-symmetry breaking are introduced. The next lightest technicolor resonances are expected to be the analogs of the vector mesons in QCD. The technivector mesons can also have color and electroweak quantum numbers and, for a theory with a small number of technifermions, are expected to have a mass in the TeV range [6].

While technicolor chiral symmetry breaking can give mass to the W and Z particles, additional interactions must be introduced to produce the masses of the standard model fermions. The most thoroughly studied mechanism for this invokes "extended technicolor" (ETC) gauge interactions [4,7]. In ETC, technicolor, color and flavor are embedded into a larger gauge group which is broken to technicolor and color at an energy scale of 100s to 1000s of TeV. The massive gauge bosons associated with this breaking mediate transitions between quarks/leptons

and technifermions, giving rise to the couplings necessary to produce fermion masses. The ETC gauge bosons also mediate transitions among technifermions themselves, leading to interactions which can explicitly break unwanted chiral symmetries and raise the masses of any light technipions. The ETC interactions connecting technifermions to quarks/leptons also mediate technipion decays to ordinary fermion pairs. Since these interactions are responsible for fermion masses, one generally expects technipions to decay to the heaviest fermions kinematically allowed (though this need not hold in all models).

In addition to quark masses, ETC interactions must also give rise to quark mixing. One expects, therefore, that there are ETC interactions coupling quarks of the same charge from different generations. A stringent limit on these flavor-changing neutral current interactions comes from K^0–$\overline{K}^0$ mixing [4]. These force the scale of ETC breaking and the corresponding ETC gauge boson masses to be in the 100-1000 TeV range (at least insofar as ETC interactions of first two generations are concerned). To obtain quark and technipion masses that are large enough then requires an enhancement of the technifermion condensate over that expected naively by scaling from QCD. Such an enhancement can occur if the technicolor gauge coupling runs very slowly, or "walks" [8]. Many technifermions typically are needed to make the TC coupling walk, implying that the technicolor scale and, in particular, the technivector mesons may be much lighter than 1 TeV [3,9]. It should also be noted that there is no reliable calculation of electroweak parameters in a walking technicolor theory, and the values of precisely measured electroweak quantities [10] cannot directly be used to constrain the models. Recently, progress has been made in constructing a complete theory of fermion masses (including neutrino masses) in the context of extended technicolor [11].

In existing colliders, technivector mesons are dominantly produced when an off-shell standard model gauge-boson "resonates" into a technivector meson with the same quantum numbers [12]. The technivector mesons may then decay, in analogy with $\rho \to \pi\pi$, to pairs of technipions. However, in walking technicolor the technipion masses may be increased to the point that the decay of a technirho to pairs of technipions is kinematically forbidden [9]. In this case the decay to a technipion and a longitudinally polarized weak boson (an "eaten" Goldstone boson) may be preferred, and the technivector meson would be very narrow. Alternatively, the technivector may also decay, in analogy with the decay $\rho \to \pi\gamma$, to a technipion plus a photon, gluon, or transversely polarized weak gauge boson. Finally, in analogy with the decay $\rho \to e^+e^-$, the technivector meson may resonate back to an off-shell gluon or electroweak gauge boson, leading to a decay into a pair of leptons, quarks, or gluons.

When comparing the various results presented in this review, one should be aware that the more recent analyses [19,20] make use of newer calculations [13] of technihadron production and decay, as implemented in PYTHIA version 6.126

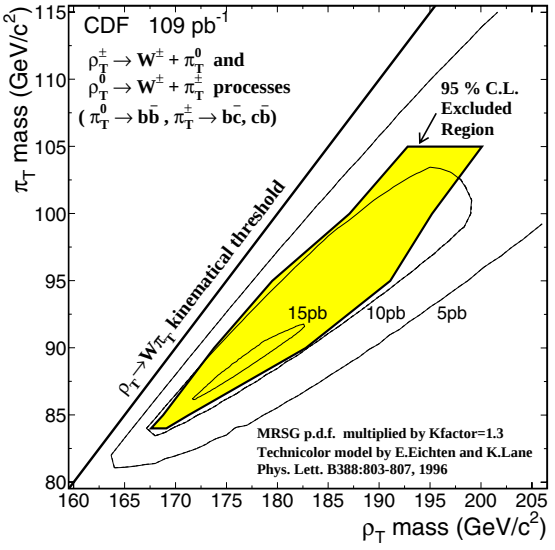

Figure 1: 95% CL exclusion region [16] for a light technirho decaying to $W^{\pm}$ and a π_T, and in which the π_T decays to two jets including at least one b quark. See full-color version on color pages at end of book.

and higher [14]. The results obtained with older cross section calculations are not always directly comparable.

If the dominant decay mode of the technirho is $W_L\pi_T$, promising signal channels [15] are $\rho_T^{\pm} \to W^{\pm}\pi_T^0$ and $\rho_T^0 \to W^{\pm}\pi_T^{\mp}$. If we assume that the technipions decay to $b\overline{b}$ (neutral) and $b\overline{c}$ (charged), then both channels yield a signal of $W(\ell\nu) + 2$jets, with one or more heavy flavor tags. The CDF collaboration has carried out a search in this final state [16] based on Run I data and using PYTHIA [17] version 6.1 for the signal simulation. The results are shown in Figure 1. We see that the search is sensitive to $\sigma \cdot B \gtrsim 10$ pb and that roughly $170 < m_{\rho_T} < 190$ GeV is excluded at the 95% confidence level, for $m_{\pi_T} \approx m_{\rho_T}/2$. For an integrated luminosity of 2 fb^{-1} in Run II, the 5σ discovery reach extends to $m_{\rho_T} = 210$ GeV and $m_{\pi_T} = 110$ GeV, while the 95% exclusion sensitivity will extend to $m_{\rho_T} = 250$ GeV and $m_{\pi_T} = 145$ GeV.

CDF has also searched [18] for the process $\omega_T^0 \to \gamma\pi_T^0$, yielding a signal of a hard photon plus two jets, with one or more heavy flavor tags. The sensitivity to $\sigma \cdot B$ is of order 1 pb. The excluded region is shown in Fig. 2 and is roughly $140 < m_{\omega_T} < 290$ GeV at the 95% level, for $m_{\pi_T} \approx m_{\omega_T}/3$. The analysis assumes four technicolors, $Q_D = Q_U - 1 = \frac{1}{3}$ and $M_T = 100$ GeV/c^2. Here Q_U and Q_D are the charges of the lightest technifermion doublet and M_T is a dimensionful

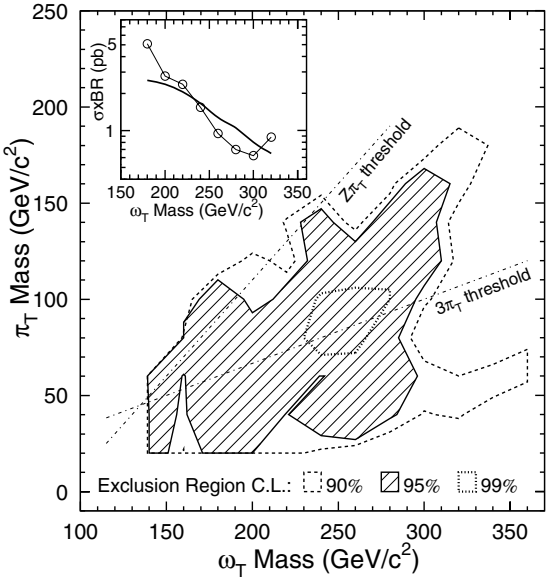

Figure 2: 95% CL exclusion region [18] for a light techniomega decaying to γ and a π_T, and in which the π_T decays to two jets including at least one b quark. (Inset: cross section limit for $m_{\pi_T} = 120$ GeV.)

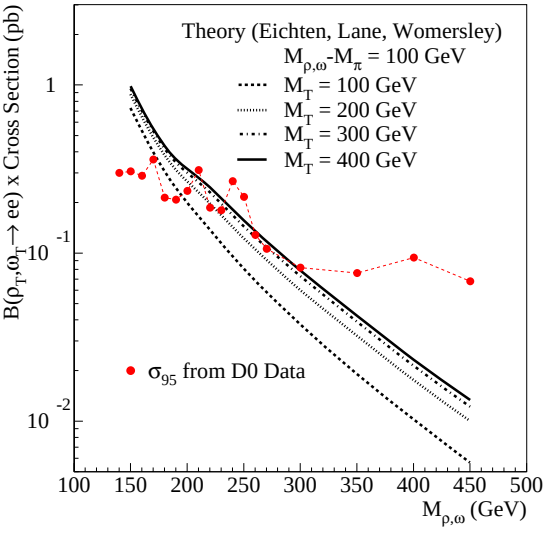

Figure 3: 95% CL cross-section limit [19] for a light techniomega and a light technirho decaying to $\ell^+\ell^-$. See full-color version on color pages at end of book.

parameter, of order 100 GeV/c^2, which controls the rate of $\rho_T, \omega_T \to \gamma\pi_T$.

The DØ experiment has searched [19] for low-scale technicolor resonances ρ_T and ω_T decaying to dileptons, using an inclusive e^+e^- sample from Run I. In the search, the ρ_T and ω_T are assumed to be degenerate in mass. The absence of structure in the dilepton invariant mass distribution is then used to set limits. Masses $m_{\rho_T} = m_{\omega_T} \lesssim 200$ GeV are excluded, provided either $m_{\rho_T} < m_{\pi_T} + m_W$, or $M_T > 200$ GeV (as shown in Fig. 3). With 2 fb^{-1} of data in Run II, the sensitivity will extend to $m_{\rho_T} = m_{\omega_T} \approx 500$ GeV.

DELPHI [20] has reported a search for technicolor production in 452 pb^{-1} of e^+e^- data taken between 192 and 208 GeV. The analysis combines searches for $e^+e^- \to \rho_T(\gamma)$ with $\rho_T \to W_L W_L$, $\rho_T \to$ hadrons ($\pi_T\pi_T$ or $q\overline{q}$), $\rho_T \to \pi_T\gamma$, and $e^+e^- \to \rho_T^* \to W_L\pi_T$ or $\pi_T\pi_T$. Technirho masses in the range $90 < m_{\rho_T} < 206.7$ GeV are excluded, while technipion masses $m_{\pi_T} < 79.8$ GeV are ruled out independent of the parameters of the technicolor model.

Searches have also been carried out at the Tevatron for colored technihadron resonances [21,22]. CDF has used a search for structure in the dijet invariant mass spectrum to set limits on a color-octet technirho ρ_{T8} produced by an off-shell gluon and decaying to two real quarks or gluons. As shown in Fig. 5 masses $260 < m_{\rho_{T8}} < 480$ GeV are excluded; in Run II the limits will improve to cover the whole mass range up to about 0.8 TeV [23].

The CDF second and third-generation leptoquark searches (see Refs. [24,25]) have also been interpreted in terms of the complementary ρ_{T8} decay mode: $p\overline{p} \to \rho_{T8} \to \pi_{LQ}\pi_{LQ}$. Here π_{LQ} denotes a color-triplet technipion carrying both color and lepton number, assumed to decay to $b\nu$ or $c\nu$ [25] or to a τ plus a quark [24]. The searches exclude technirho masses $m_{\rho_{T8}}$ less than 510 GeV ($\pi_{LQ} \to c\nu$), 600 GeV ($\pi_{LQ} \to b\nu$), and 465 GeV ($\pi_{LQ} \to \tau q$) for technipion masses up to $m_{\rho_{T8}}/2$. Figure 6 shows the $\pi_{LQ} \to b\nu$ exclusion region. (Leptoquark masses $m_{\pi_{LQ}}$ less than 123 GeV ($c\nu$), 148 GeV ($b\nu$), and 99 GeV (τq) are already ruled out by standard continuum-production leptoquark searches).

Recently, it has been demonstrated that there is substantial uncertainty in the theoretical estimate of the ρ_{T8} production cross section at the Tevatron and that the cross section may be as much as an order of magnitude lower than the naive vector meson dominance estimate [26]. To establish the range of allowed masses, these limits will need to be redone with a reduced theoretical cross section.

II. Top Condensate and Related Models

The top quark is much heavier than other fermions and must be more strongly coupled to the symmetry-breaking sector. It is natural to consider whether some or all of electroweak-symmetry breaking is due to a condensate of top quarks [3,27].

See key on page 323

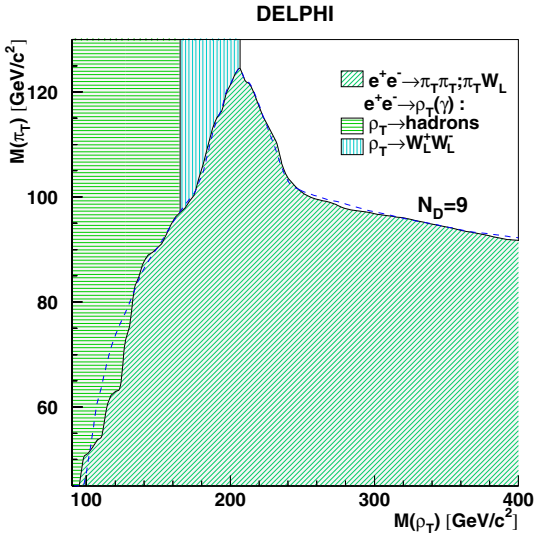

Figure 4: 95% CL exclusion region [20] in the technirho-technipion mass plane obtained from searches by the DELPHI collaboration at LEP 2, for nine technifermion doublets. The dashed line shows the expected limit for the 4-jet analysis. See full-color version on color pages at end of book.

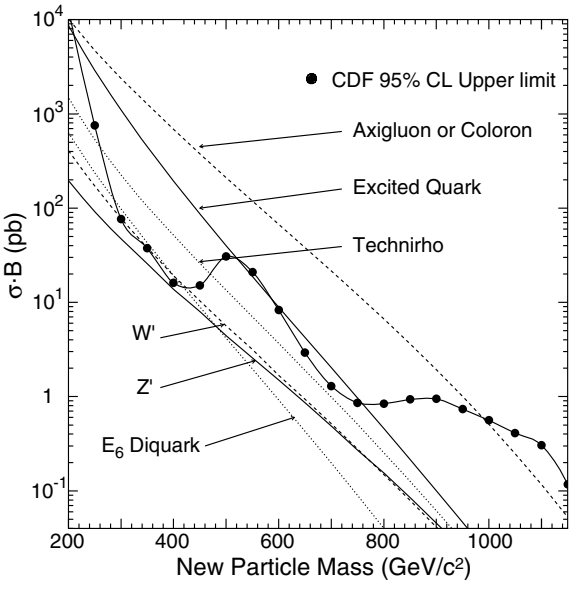

Figure 5: 95% CL Cross-section limits [22] for a technirho decaying to two jets at the Tevatron.

Top-quark condensation alone, without additional fermions, seems to produce a top-quark mass larger [28] than observed experimentally, and is therefore not favored. Topcolor assisted technicolor [29] combines technicolor and top-condensation. In addition to technicolor, which provides the bulk of electroweak symmetry breaking, top-condensation and the top quark mass arise predominantly from "topcolor," a new QCD-like interaction which couples strongly to the third generation of quarks. An additional, strong, U(1) interaction (giving rise to a topcolor Z') precludes the formation of a b-quark condensate.

CDF has searched [30] for the "topgluon," a massive color-octet vector which couples preferentially to the third generation, in the mode $p\overline{p} \to g_t \to b\overline{b}$. The results are shown in Fig. 7. Topgluon masses from approximately 0.3 to 0.6 TeV are excluded at 95% confidence level, for topgluon widths in the range $0.3m_{g_t} < \Gamma < 0.7m_{g_t}$. Results have also been reported by CDF [31] on a search for narrow resonances in the $t\overline{t}$ invariant mass distribution. The cross section limit is shown in Fig. 8 and excludes a leptophobic topcolor Z' with masses less than 480 (780) GeV/c^2, for the case where its width $\Gamma = 0.012(0.04)\, m_{Z'}$. (DØ has carried out a similar search, with greater sensitivity [32], but has not derived comparable Z' mass limits.) A broad topgluon could also be detected in the same final state, though no results are yet available. In Run II, the Tevatron [23] should be sensitive to topgluon and topcolor Z' masses up to of order 1 TeV in $b\overline{b}$ and $t\overline{t}$ final states. A detailed theoretical analysis of B–$\overline{B}$ mixing and light quark mass generation in top-color assisted technicolor shows that, at least in some models, the topgluon and Z' boson masses must be greater than about 5 TeV [33].

The top-quark seesaw model of electroweak symmetry breaking [34] is a variant of the original top-condensate idea which reconciles top-condensation with a lighter top-quark mass. Such a model can easily be consistent with precision electroweak tests, either because the spectrum includes a light composite Higgs [35] or because additional interactions allow for a heavier Higgs [36]. Such theories may arise naturally from gauge fields propagating in compact extra spatial dimensions [37].

A variant of topcolor-assisted technicolor is flavor-universal, in which the topcolor SU(3) gauge bosons, called colorons, couple equally to all quarks [38]. Flavor-universal versions of the seesaw model [39] incorporating a gauged flavor symmetry are also possible. In these models *all* left-handed quarks (and possibly leptons as well) participate in electroweak symmetry-breaking condensates with separate (one for each flavor) right-handed weak singlets, and the different fermion masses arise by adjusting the parameters which control the mixing of each fermion with the corresponding condensate.

A prediction of these flavor-universal models, is the existence of new heavy gauge bosons, coupling to color or flavor, at relatively low mass scales. The absence of an excess of high-E_T

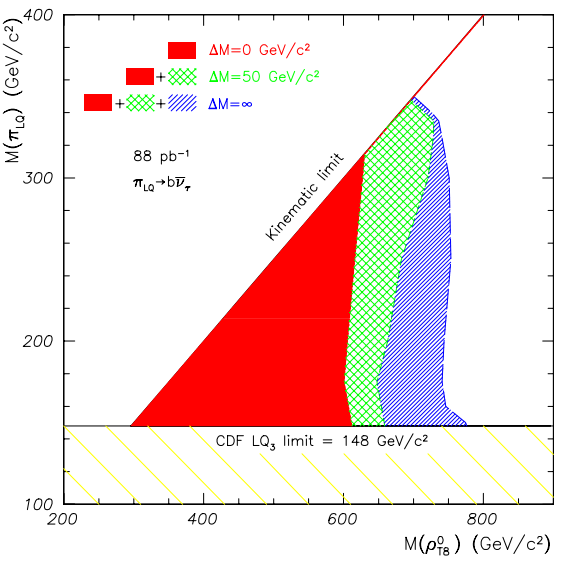

Figure 6: 95% CL exclusion region [25] in the technirho-technipion mass plane for pair produced technipions, with leptoquark couplings, decaying to $b\nu$. See full-color version on color pages at end of book.

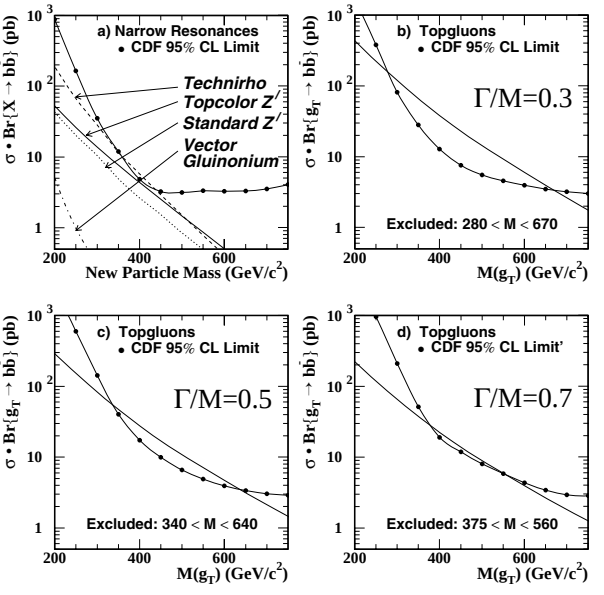

Figure 7: Tevatron limits [30] on new particles decaying to $b\bar{b}$: narrow resonances and topgluons for various widths.

jets in DØ data [40] has been used to constrain strongly-coupled flavor-universal colorons (massive color-octet bosons coupling to all quarks). A mass limit of between 0.8 and 3.5 TeV is set [41] depending on the coloron-gluon mixing angle. Precision electroweak measurements constrain [42] the masses of these new gauge bosons to be greater than 1–3 TeV in a variety of models, for strong couplings.

Recently a new class [43] of composite Higgs model [44], dubbed "Little Higgs Theory," has been developed which give rise to naturally light Higgs bosons without supersymmetry [46]. Inspired by discretized versions of higher-dimensional gauge theory [45], these models are based on the chiral symmetries of "theory space." The models involve extended gauge groups and novel gauge symmetry breaking patterns. The new chiral symmetries prevent large corrections to the Higgs boson mass, and allow the scale (Λ) of the underlying strong dynamics giving rise to the composite particles to be as large as 10 TeV. These models typically require new gauge bosons and fermions, and possibly additional composite scalars beyond the Higgs, in the TeV mass range.

Table 1: Summary of the mass limits. Symbols are defined in the text.

Process	Excluded mass range	Decay channels	Ref.
$p\overline{p} \to \rho_T \to W\pi_T$	$170 < m_{\rho_T} < 190$ GeV for $m_{\pi_T} \approx m_{\rho_T}/2$	$\rho_T \to W\pi_T$ $\pi_T^0 \to b\overline{b}$ $\pi_T^\pm \to b\overline{c}$	[16]
$p\overline{p} \to \omega_T \to \gamma\pi_T$	$140 < m_{\omega_T} < 290$ GeV for $m_{\pi_T} \approx m_{\omega_T}/3$ and $M_T = 100$ GeV	$\omega_T \to \gamma\pi_T$ $\pi_T^0 \to b\overline{b}$ $\pi_T^\pm \to b\overline{c}$	[18]
$p\overline{p} \to \omega_T/\rho_T$	$m_{\omega_T} = m_{\rho_T} < 203$ GeV for $m_{\omega_T} < m_{\pi_T} + m_W$ or $M_T > 200$ GeV	$\omega_T/\rho_T \to \ell^+\ell^-$	[19]
$e^+e^- \to \omega_T/\rho_T$	$90 < m_{\rho_T} < 206.7$ GeV $m_{\pi_T} < 79.8$ GeV	$\rho_T \to WW$, $W\pi_T$, $\pi_T\pi_T$, $\gamma\pi_T$, hadrons	[20]
$p\overline{p} \to \rho_{T8}$	$260 < m_{\rho_{T8}} < 480$ GeV	$\rho_{T8} \to q\overline{q}$, gg	[22]
$p\overline{p} \to \rho_{T8}$	$m_{\rho_{T8}} < 510$ GeV	$\pi_{LQ} \to c\nu$	[25]
$\to \pi_{LQ}\pi_{LQ}$	$m_{\rho_{T8}} < 600$ GeV	$\pi_{LQ} \to b\nu$	[25]
	$m_{\rho_{T8}} < 465$ GeV	$\pi_{LQ} \to \tau q$	[24]
$p\overline{p} \to g_t$	$0.3 < m_{g_t} < 0.6$ TeV for $0.3m_{g_t} < \Gamma < 0.7m_{g_t}$	$g_t \to b\overline{b}$	[30]
$p\overline{p} \to Z'$	$m_{Z'} < 480$ GeV for $\Gamma = 0.012m_{Z'}$ $m_{Z'} < 780$ GeV for $\Gamma = 0.04m_{Z'}$	$Z' \to t\overline{t}$	[31]

[1] CHEKANOV 02B search for color octet techni-π P decaying into dijets in ep collisions. See their Fig. 5 for the limit on $\sigma(ep \to eP X)\cdot B(P \to 2j)$.

[2] ABAZOV 01B searches for vector techni-resonances (ρ_T,ω_T) decaying to e^+e^-. The limit assumes $M_{\rho_T} = M_{\omega_T} < M_{\pi_T} + M_W$.

[3] The limit is independent of the π_T mass. See their Fig. 9 and Fig. 10 for the exclusion plot in the M_{ρ_T}–M_{π_T} plane. ABDALLAH 01 limit on the techni-pion mass is $M_{\pi_T} > 79.8$ GeV for N_D=2, assuming its point-like coupling to gauge bosons.

[4] AFFOLDER 00F search for ρ_T decaying into $W\pi_T$ or $\pi_T\pi_T$ with $W \to \ell\nu$ and $\pi_T \to \overline{b}b$, $\overline{b}c$. See Fig. 1 in the above Note on "Dynamical Electroweak Symmetry Breaking" for the exclusion plot in the M_{ρ_T}–M_{π_T} plane.

[5] AFFOLDER 00K search for the ρ_{T8} decaying into $\pi_{LQ}\pi_{LQ}$ with $\pi_{LQ} \to b\nu$. For $\pi_{LQ} \to c\nu$, the limit is $M_{\rho_{T8}}$ >510 GeV. See their Fig. 2 and Fig. 3 for the exclusion plot in the $M_{\rho_{T8}}$–$M_{\pi_{LQ}}$ plane.

[6] AFFOLDER 00L search for top-color $Z'_{\rm top}$ decaying into $\overline{t}t$. The quoted limit is for $Z'_{\rm top}$ with decay width Γ=0.012 $M_{Z'}$. For Γ=0.04 $M_{Z'}$ the limit becomes 780 GeV.

[7] ABE 99F search for a new particle X decaying into $b\overline{b}$ in $p\overline{p}$ collisions at $E_{\rm cm}$= 1.8 TeV. See Fig. 7 in the above Note on "Dynamical Electroweak Symmetry Breaking" for the upper limit on $\sigma(p\overline{p} \to X)\times B(X \to b\overline{b})$. ABE 99F also exclude top gluons of width Γ=0.3M in the mass interval 280 <M< 670 GeV, of width Γ=0.5M in the mass interval 340 <M< 640 GeV, and of width Γ=0.7M in the mass interval 375 <M< 560 GeV.

[8] ABE 99H search for the color-octet techni-ρ decaying into a pair of color-triplet technipions which subsequently decay into τ+ jet. See Fig. 6 in the above Note on "Dynamical Electroweak Symmetry Breaking" for the exclusion plot in the $M_{\rho_{T8}}$–$M_{\pi_{LQ}}$ plane.

[9] ABE 99N search for the techni-ω decaying into $\gamma\pi_T$. The technipion is assumed to decay $\pi_T \to b\overline{b}$. See Fig. 2 in the above Note on "Dynamical Electroweak Symmetry Breaking" for the exclusion plot in the M_{ω_T}–M_{π_T} plane.

[10] ABE 97G search for a new particle X decaying into dijets in $p\overline{p}$ collisions at $E_{\rm cm}$= 1.8 TeV. See Fig. 5 in the above Note on "Dynamical Electroweak Symmetry Breaking" for the upper limit on $\sigma(p\overline{p} \to X)\times B(X \to 2j)$.

Quark and Lepton Compositeness, Searches for

SEARCHES FOR QUARK AND LEPTON COMPOSITENESS

Revised 2001 by K. Hagiwara (KEK), and K. Hikasa and M. Tanabashi (Tohoku University).

If quarks and leptons are made of constituents, then at the scale of constituent binding energies, there should appear new interactions among quarks and leptons. At energies much below the compositeness scale (Λ), these interactions are suppressed by inverse powers of Λ. The dominant effect should come from the lowest dimensional interactions with four fermions (contact terms), whose most general chirally invariant form reads [1]

$$L = \frac{g^2}{2\Lambda^2}\left[\eta_{LL}\,\overline{\psi}_L\gamma_\mu\psi_L\,\overline{\psi}_L\gamma^\mu\psi_L + \eta_{RR}\,\overline{\psi}_R\gamma_\mu\psi_R\,\overline{\psi}_R\gamma^\mu\psi_R + 2\eta_{LR}\,\overline{\psi}_L\gamma_\mu\psi_L\,\overline{\psi}_R\gamma^\mu\psi_R\right] . \quad (1)$$

Chiral invariance provides a natural explanation why quark and lepton masses are much smaller than their inverse size Λ. We may determine the scale Λ unambiguously by using the above form of the effective interactions; the conventional method [1] is to fix its scale by setting $g^2/4\pi = g^2(\Lambda)/4\pi = 1$ for the new strong interaction coupling and by setting the largest magnitude of the coefficients $\eta_{\alpha\beta}$ to be unity. In the following, we denote

$$\begin{aligned}
\Lambda &= \Lambda^\pm_{LL} \quad \text{for} \quad (\eta_{LL}, \eta_{RR}, \eta_{LR}) = (\pm1, 0, 0) ,\\
\Lambda &= \Lambda^\pm_{RR} \quad \text{for} \quad (\eta_{LL}, \eta_{RR}, \eta_{LR}) = (0, \pm1, 0) ,\\
\Lambda &= \Lambda^\pm_{VV} \quad \text{for} \quad (\eta_{LL}, \eta_{RR}, \eta_{LR}) = (\pm1, \pm1, \pm1) ,\\
\Lambda &= \Lambda^\pm_{AA} \quad \text{for} \quad (\eta_{LL}, \eta_{RR}, \eta_{LR}) = (\pm1, \pm1, \mp1) , \quad (2)
\end{aligned}$$

as typical examples. Such interactions can arise by constituent interchange (when the fermions have common constituents, *e.g.*, for $ee \to ee$) and/or by exchange of the binding quanta (whenever binding quanta couple to constituents of both particles).

Another typical consequence of compositeness is the appearance of excited leptons and quarks (ℓ^* and q^*). Phenomenologically, an excited lepton is defined to be a heavy lepton which shares leptonic quantum number with one of the existing leptons (an excited quark is defined similarly). For example, an excited electron e^* is characterized by a nonzero transition-magnetic coupling with electrons. Smallness of the lepton mass and the success of QED prediction for g–2 suggest chirality conservation, *i.e.*, an excited lepton should not couple to both left- and right-handed components of the corresponding lepton.

Excited leptons may be classified by SU(2)×U(1) quantum numbers. Typical examples are:

1. Sequential type

$$\begin{pmatrix}\nu^*\\ \ell^*\end{pmatrix}_L , \qquad [\nu^*_R] , \qquad \ell^*_R .$$

ν^*_R is necessary unless ν^* has a Majorana mass.

2. Mirror type

$$[\nu_L^*]\ , \qquad \ell_L^*\ , \qquad \begin{pmatrix}\nu^*\\ \ell^*\end{pmatrix}_R\ .$$

3. Homodoublet type

$$\begin{pmatrix}\nu^*\\ \ell^*\end{pmatrix}_L\ , \qquad \begin{pmatrix}\nu^*\\ \ell^*\end{pmatrix}_R\ .$$

Similar classification can be made for excited quarks.

Excited fermions can be pair produced via their gauge couplings. The couplings of excited leptons with Z are listed in the following table (for notation see Eq. (1) in "Standard Model of Electroweak Interactions"):

	Sequential type	Mirror type	Homodoublet type
V^{ℓ^*}	$-\frac{1}{2}+2\sin^2\theta_W$	$-\frac{1}{2}+2\sin^2\theta_W$	$-1+2\sin^2\theta_W$
A^{ℓ^*}	$-\frac{1}{2}$	$+\frac{1}{2}$	0
$V^{\nu_D^*}$	$+\frac{1}{2}$	$+\frac{1}{2}$	$+1$
$A^{\nu_D^*}$	$+\frac{1}{2}$	$-\frac{1}{2}$	0
$V^{\nu_M^*}$	0	0	—
$A^{\nu_M^*}$	$+1$	-1	—

Here ν_D^* (ν_M^*) stands for Dirac (Majorana) excited neutrino. The corresponding couplings of excited quarks can be easily obtained. Although form factor effects can be present for the gauge couplings at $q^2 \neq 0$, they are usually neglected.

In addition, transition magnetic type couplings with a gauge boson are expected. These couplings can be generally parameterized as follows:

$$\begin{aligned}\mathcal{L} = {} & \frac{\lambda_\gamma^{(f^*)} e}{2m_{f^*}}\,\overline{f}^*\sigma^{\mu\nu}(\eta_L\tfrac{1-\gamma_5}{2}+\eta_R\tfrac{1+\gamma_5}{2})f F_{\mu\nu} \\ & + \frac{\lambda_Z^{(f^*)} e}{2m_{f^*}}\,\overline{f}^*\sigma^{\mu\nu}(\eta_L\tfrac{1-\gamma_5}{2}+\eta_R\tfrac{1+\gamma_5}{2})f Z_{\mu\nu} \\ & + \frac{\lambda_W^{(\ell^*)} g}{2m_{\ell^*}}\,\overline{\ell}^*\sigma^{\mu\nu}\tfrac{1-\gamma_5}{2}\nu W_{\mu\nu} \\ & + \frac{\lambda_W^{(\nu^*)} g}{2m_{\nu^*}}\,\overline{\nu}^*\sigma^{\mu\nu}(\eta_L\tfrac{1-\gamma_5}{2}+\eta_R\tfrac{1+\gamma_5}{2})\ell\, W_{\mu\nu}^\dagger \\ & + \text{h.c.}\ , \end{aligned} \tag{3}$$

where $g = e/\sin\theta_W$, $F_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu$ is the photon field strength, $Z_{\mu\nu} = \partial_\mu Z_\nu - \partial_\nu Z_\mu$, *etc.* The normalization of the coupling is chosen such that

$$\max(|\eta_L|, |\eta_R|) = 1\ .$$

Chirality conservation requires

$$\eta_L \eta_R = 0\ . \tag{4}$$

Some experimental analyses assume the relation $\eta_L = \eta_R = 1$, which violates chiral symmetry. We encode the results of such analyses if the crucial part of the cross section is proportional to the factor $\eta_L^2 + \eta_R^2$ and the limits can be reinterpreted as those for chirality conserving cases $(\eta_L, \eta_R) = (1, 0)$ or $(0, 1)$ after rescaling λ.

These couplings in Eq. (3) can arise from SU(2)×U(1)-invariant higher-dimensional interactions. A well-studied model is the interaction of homodoublet type ℓ^* with the Lagrangian [2,3]

$$\mathcal{L} = \frac{1}{2\Lambda}\overline{L}^*\sigma^{\mu\nu}(g f\tfrac{\tau^a}{2}W_{\mu\nu}^a + g' f' Y B_{\mu\nu})\tfrac{1-\gamma_5}{2}L + \text{h.c.}\ , \tag{5}$$

where L denotes the lepton doublet (ν, ℓ), Λ is the compositeness scale, g, g' are SU(2) and U(1)$_Y$ gauge couplings, and $W_{\mu\nu}^a$ and $B_{\mu\nu}$ are the field strengths for SU(2) and U(1)$_Y$ gauge fields. The same interaction occurs for mirror-type excited leptons. For sequential-type excited leptons, the ℓ^* and ν^* couplings become unrelated, and the couplings receive the extra suppression of $(250\,\text{GeV})/\Lambda$ or m_{L^*}/Λ. In any case, these couplings satisfy the relation

$$\lambda_W = -\sqrt{2}\sin^2\theta_W(\lambda_Z\cot\theta_W + \lambda_\gamma)\ . \tag{6}$$

Additional coupling with gluons is possible for excited quarks:

$$\begin{aligned}\mathcal{L} = {} & \frac{1}{2\Lambda}\overline{Q}^*\sigma^{\mu\nu}\left(g_s f_s\tfrac{\lambda^a}{2}G_{\mu\nu}^a + g f\tfrac{\tau^a}{2}W_{\mu\nu}^a + g' f' Y B_{\mu\nu}\right) \\ & \times \tfrac{1-\gamma_5}{2}Q + \text{h.c.}\ , \end{aligned} \tag{7}$$

where Q denotes a quark doublet, g_s is the QCD gauge coupling, and $G_{\mu\nu}^a$ the gluon field strength.

It should be noted that the electromagnetic radiative decay of $\ell^*(\nu^*)$ is forbidden if $f = -f'$ ($f = f'$). These two possibilities ($f = f'$ and $f = -f'$) are investigated in many analyses of the LEP experiments above the Z pole.

Several different conventions are used by LEP experiments on Z pole to express the transition magnetic couplings. To facilitate comparison, we re-express these in terms of λ_Z and λ_γ using the following relations and taking $\sin^2\theta_W = 0.23$. We assume chiral couplings, *i.e.*, $|c| = |d|$ in the notation of Ref. 2.

1. ALEPH (charged lepton and neutrino)

$$\lambda_Z^{\text{ALEPH}} = \frac{1}{2}\lambda_Z \quad (1990\ \text{papers}) \tag{8a}$$

$$\frac{2c}{\Lambda} = \frac{\lambda_Z}{m_{\ell^*}\,[\text{or } m_{\nu^*}]} \quad (\text{for } |c| = |d|) \tag{8b}$$

2. ALEPH (quark)

$$\lambda_u^{\text{ALEPH}} = \frac{\sin\theta_W\cos\theta_W}{\sqrt{\frac{1}{4}-\frac{2}{3}\sin^2\theta_W+\frac{8}{9}\sin^4\theta_W}}\,\lambda_Z = 1.11\lambda_Z \tag{9}$$

3. L3 and DELPHI (charged lepton)

$$\lambda^{\text{L3}} = \lambda_Z^{\text{DELPHI}} = -\frac{\sqrt{2}}{\cot\theta_W - \tan\theta_W}\,\lambda_Z = -1.10\lambda_Z \tag{10}$$

4. L3 (neutrino)

$$f_Z^{\rm L3} = \sqrt{2}\lambda_Z \qquad (11)$$

5. OPAL (charged lepton)

$$\frac{f^{\rm OPAL}}{\Lambda} = -\frac{2}{\cot\theta_W - \tan\theta_W}\,\frac{\lambda_Z}{m_{\ell^*}} = -1.56\,\frac{\lambda_Z}{m_{\ell^*}} \qquad (12)$$

6. OPAL (quark)

$$\frac{f^{\rm OPAL}c}{\Lambda} = \frac{\lambda_Z}{2m_{q^*}} \quad ({\rm for}\,|c| = |d|) \qquad (13)$$

7. DELPHI (charged lepton)

$$\lambda_\gamma^{\rm DELPHI} = -\frac{1}{\sqrt{2}}\,\lambda_\gamma \qquad (14)$$

If leptons are made of color triplet and antitriplet constituents, we may expect their color-octet partners. Transitions between the octet leptons (ℓ_8) and the ordinary lepton (ℓ) may take place via the dimension-five interactions

$$\mathcal{L} = \frac{1}{2\Lambda}\sum_\ell \left\{ \overline{\ell}_8^\alpha\, g_S\, F_{\mu\nu}^\alpha\, \sigma^{\mu\nu}\left(\eta_L\,\ell_L + \eta_R\,\ell_R\right) + h.c.\right\} \qquad (15)$$

where the summation is over charged leptons and neutrinos. The leptonic chiral invariance implies $\eta_L\,\eta_R = 0$ as before.

[28] CHEUNG 01B is an update of BARGER 98E.

[29] BARATE 00I limits are from R_b and jet-charge asymmetry at 130–183 GeV.

[30] ABREU 99A limits are from flavor-tagged $e^+e^- \to q\overline{q}$ cross section at 130–172 GeV.

[31] ADLOFF 03 limits are from the $d\sigma/dQ^2$ measurement of $e^\pm p \to e^\pm X$.

[32] ACHARD 02J limit is from the bound on the $e^+e^- \to t\overline{c}$ cross section. $\Lambda_{LL} = \Lambda_{LR} = \Lambda_{RL} = \Lambda_{RR}$ and m_t = 175 GeV are assumed.

[33] ABBIENDI 00R limits are from $e^+e^- \to q\overline{q}$ cross section at $\sqrt{s}$= 130–189 GeV.

[34] ACCIARRI 00P limit is from $e^+e^- \to qq$ cross section at $\sqrt{s}$=130–189 GeV.

[35] ADLOFF 00 limits are from the Q^2 spectrum measurement of $e^+p \to e^+X$.

[36] BARATE 00I limits are from $e^+e^- \to q\overline{q}$ cross section and jet-charge asymmetry at 130–183 GeV.

[37] BREITWEG 00B limits are from Q^2 spectrum measurement of e^+p collisions. See their Table 3 for the limits of various models.

[38] ABBIENDI 99 limits are from $e^+e^- \to q\overline{q}$ cross section at 130–136, 161–172, 183 GeV.

[39] ABBIENDI 99 limits are from R_b at 130–136, 161–172, 183 GeV.

[40] ABBOTT 99D limits are from e^+e^- mass distribution in $p\overline{p} \to e^+e^-X$ at E_{cm}= 1.8 TeV.

[41] ZARNECKI 99 use data from HERA, LEP, Tevatron, and various low-energy experiments.

[42] ACCIARRI 98J limits are from $e^+e^- \to q\overline{q}$ cross section at E_{cm}= 130–172 GeV.

[43] ACKERSTAFF 98V limits are from $e^+e^- \to q\overline{q}$ at E_{cm}= 130–172 GeV.

[44] ACKERSTAFF 98V limits are from R_b measurements at E_{cm}= 130–172 GeV.

[45] BARGER 98E use data from HERA, LEP, Tevatron, and various low-energy experiments.

[46] ABE 97T limits are from e^+e^- mass distribution in $\overline{p}p \to e^+e^-X$ at E_{cm}=1.8 TeV.

[47] ACKERSTAFF 97C limits are from $e^+e^- \to q\overline{q}$ cross section at E_{cm} = 130–136 GeV and 161 GeV.

[48] ACKERSTAFF 97C limits are R_b measurements at E_{cm} = 133 GeV and 161 GeV.

[49] DEANDREA 97 limit is from atomic parity violation of cesium. The limit is eluded if the contact interactions are parity conserving.

[50] AID 95 limits are from the Q^2 spectrum measurement of $ep \to eX$.

[51] ABE 91D limits are from e^+e^- mass distribution in $p\overline{p} \to e^+e^-X$ at E_{cm} = 1.8 TeV.

[52] ADACHI 91 limits are from differential jet cross section. Universality of $\Lambda(eeqq)$ for five flavors is assumed.

[53] BEHREND 91C is from data at E_{cm} = 35–43 GeV.

[54] ABE 89L limits are from jet charge asymmetry. Universality of $\Lambda(eeqq)$ for five flavors is assumed.

[55] The HAGIWARA 89 limit is derived from forward-backward asymmetry measurements of D/D^* mesons by ALTHOFF 83C, BARTEL 84E, and BARINGER 88.

[56] The HAGIWARA 89 limit is derived from forward-backward asymmetry measurement of b hadrons by BARTEL 84D.

>6.5		[60]	DIAZCRUZ	94	RVUE	$\Lambda^-_{LL}(\tau\nu_\tau \mu\nu_\mu)$

[58] JODIDIO 86 limit is from $\mu^+ \to \overline{\nu}_\mu e^+\nu_e$. Chirality invariant interactions $L = (g^2/\Lambda^2)$ $[\eta_{LL}\ (\overline{\nu}_{\mu L}\gamma^\alpha\mu_L)\ (\overline{e}_L\gamma_\alpha\nu_{eL}) + \eta_{LR}\ (\overline{\nu}_{\mu L}\gamma^\alpha\nu_{eL}\ (\overline{e}_R\gamma_\alpha\mu_R)]$ with $g^2/4\pi = 1$ and $(\eta_{LL},\eta_{LR}) = (0,\pm1)$ are taken. No limits are given for $\Lambda^{\pm}_{LL}$ with $(\eta_{LL},\eta_{LR}) = (\pm1,0)$. For more general constraints with right-handed neutrinos and chirality nonconserving contact interactions, see their text.

[59] DIAZCRUZ 94 limits are from $\Gamma(\tau \to e\nu\nu)$ and assume flavor-dependent contact interactions with $\Lambda(\tau\nu_\tau e\nu_e) \ll \Lambda(\mu\nu_\mu e\nu_e)$.

[60] DIAZCRUZ 94 limits are from $\Gamma(\tau \to \mu\nu\nu)$ and assume flavor-dependent contact interactions with $\Lambda(\tau\nu_\tau\mu\nu_\mu) \ll \Lambda(\mu\nu_\mu e\nu_e)$.

[62] The quoted limit is from inclusive dijet mass spectrum in $p\overline{p}$ collisions at E_{cm}=1.8 TeV. ABBOTT 99C also obtain $\Lambda^{-}_{LL} > 2.4$ TeV. All quarks are assumed composite.

[63] The quoted limit for ABBOTT 00E is from H_T distribution in $p\overline{p}$ collisions at E_{cm}=1.8 TeV. CTEQ4M PDF and $\mu = E_T^{max}$ are assumed. For limits with different assumptions, see their Tables 2 and 3. All quarks are assumed composite.

[64] ABBOTT 98G limit is from dijet angular distribution in $p\overline{p}$ collisions at E_{cm}= 1.8 TeV. All quarks are assumed composite.

[65] BERTRAM 98 obtain limit on the scale of color-octet axial-vector flavor-universal contact interactions: $\Lambda_{A8} > 2.1$ TeV. They also obtain a limit $\Lambda_{V8} > 2.4$ TeV on a color-octet flavor-universal vectorial contact interaction.

[66] ABE 96 finds that the inclusive jet cross section for $E_T > 200$ GeV is significantly higher than the $\mathcal{O}(\alpha_s^3)$ perturbative QCD prediction. This could be interpreted as the effect of a contact interaction with $\Lambda_{LL} \sim 1.6$ TeV. However, ABE 96 state that uncertainty in the parton distribution functions, higher-order QCD corrections, and the detector calibration may possibly account for the effect.

[67] ABE 96S limit is from dijet angular distribution in $p\overline{p}$ collisions at E_{cm} = 1.8 TeV. The limit for Λ^{-}_{LL} is > 1.4 TeV. ABE 96S also obtain limits for flavor symmetric contact interactions among all quark flavors: $\Lambda^{+}_{LL} > 1.8$ TeV and $\Lambda^{-}_{LL} > 1.6$ TeV.

[68] ABE 93G limit is from dijet mass distribution in $p\overline{p}$ collisions at E_{cm} = 1.8 TeV. The limit is the weakest from several choices of structure functions and renormalization scale.

[69] Limit is from inclusive jet cross-section data in $p\overline{p}$ collisions at E_{cm} = 1.8 TeV. The limit takes into account uncertainties in choice of structure functions and in choice of process scale.

[70] ABE 92M limit is from dijet angular distribution for m_{dijet} >550 GeV in $p\overline{p}$ collisions at E_{cm}=1.8 TeV.

[71] ALITTI 91B limit is from inclusive jet cross section in $p\overline{p}$ collisions at E_{cm} = 630 GeV. The limit takes into account uncertainties in choice of structure functions and in choice of process scale.

[72] ABE 89H limit is from dijet angular distribution for $m_{dijet} > 200$ GeV at the Fermilab Tevatron Collider with E_{cm} = 1.8 TeV. The QCD prediction is quite insensitive to choice of structure functions and choice of process scale.

[73] ARNISON 86C limit is from the study of inclusive high-p_T jet distributions at the CERN $\overline{p}p$ collider (E_{cm} = 546 and 630 GeV). The QCD prediction renormalized to the low-p_T region gives a good fit to the data.

[74] ARNISON 86D limit is from the study of dijet angular distribution in the range 240 < m(dijet) < 300 GeV at the CERN $\overline{p}p$ collider (E_{cm} = 630 GeV). QCD prediction using EHLQ structure function (EICHTEN 84) with Λ_{QCD} = 0.2 GeV for the choice of $Q^2 = {p_T}^2$ gives the best fit to the data.

[75] APPEL 85 limit is from the study of inclusive high-p_T jet distributions at the CERN $\overline{p}p$ collider (E_{cm} = 630 GeV). The QCD prediction renormalized to the low-p_T region gives a good description of the data.

[76] BAGNAIA 84C limit is from the study of jet p_T and dijet mass distributions at the CERN $\overline{p}p$ collider (E_{cm} = 540 GeV). The limit suffers from the uncertainties in comparing the data with the QCD prediction.

SCALE LIMITS for Contact Interactions: $\Lambda(\nu\nu qq)$

Limits are for $\Lambda^{\pm}_{LL}$ only. For other cases, see each reference.

Λ^{+}_{LL} (TeV)	Λ^{-}_{LL} (TeV)	CL%	DOCUMENT ID		TECN	COMMENT
>5.0	**>5.4**	95	[77] MCFARLAND	98	CCFR	νN scattering

[77] MCFARLAND 98 assumed a flavor universal interaction. Neutrinos were mostly of muon type.

MASS LIMITS for Excited e (e*)

Most e^+e^- experiments assume one-photon or Z exchange. The limits from some e^+e^- experiments which depend on λ have assumed transition couplings which are chirality violating ($\eta_L = \eta_R$). However they can be interpreted as limits for chirality-conserving interactions after multiplying the coupling value λ by $\sqrt{2}$; see Note.

Excited leptons have the same quantum numbers as other ortholeptons. See also the searches for ortholeptons in the "Searches for Heavy Leptons" section.

Limits for Excited e (e*) from Pair Production

These limits are obtained from $e^+e^- \to e^{*+}e^{*-}$ and thus rely only on the (electroweak) charge of e^*. Form factor effects are ignored unless noted. For the case of limits from Z decay, the e^* coupling is assumed to be of sequential type. Possible t channel contribution from transition magnetic coupling is neglected. All limits assume a dominant $e^* \to e\gamma$ decay except the limits from $\Gamma(Z)$.

For limits prior to 1987, see our 1992 edition (Physical Review **D45**, 1 June, Part II (1992)).

[78] From e^+e^- collisions at $\sqrt{s}$ = 183–209 GeV. $f = f'$ is assumed.

[79] From e^+e^- collisions at $\sqrt{s}$ = 189–209 GeV. $f = f'$ is assumed. ACHARD 03B also obtain limit for $f = -f'$: $m_{e^*} > 96.6$ GeV.

[80] From e^+e^- collisions at $\sqrt{s}$ = 192–202 GeV. f=f' is assumed. ACCIARRI 01D also obtain limit for f=$-f'$: $m_{e^*} > 93.4$ GeV.

[81] From e^+e^- collisions at $\sqrt{s}$=161–183 GeV. f=f' is assumed. ABBIENDI 00I also obtain limit for f=$-f'$ ($e^* \to \nu W$): $m_{e^*} > 86.0$ GeV.

[82] From e^+e^- collisions at $\sqrt{s}$=189 GeV. f=f' is assumed. ACCIARRI 00E also obtain limit for f=$-f'$ ($e^* \to \nu W$): $m_{e^*} > 92.6$ GeV.

[83] From e^+e^- collisions at $\sqrt{s}$= 183 GeV. f=f' is assumed. ABREU 99O also obtain limit for f=$-f'$ ($e^* \to \nu W$): $m_{e^*} > 81.3$ GeV.

[84] From e^+e^- collisions at $\sqrt{s}$=170–172 GeV. ACKERSTAFF 98C also obtain limit from $e^* \to \nu W$ decay mode: $m_{e^*} > 81.3$ GeV.

[85] BARATE 98U obtain limits on the form factor. See their Fig. 14 for limits in mass-form factor plane.

[86] From e^+e^- collisions at $\sqrt{s}$= 161 GeV.

[87] ABREU 97B also obtain limit from charged current decay mode $e^* \to \nu W$, $m_{e^*} > 70.9$ GeV.

[88] ABREU 97B also obtain limit from charged current decay mode $e^* \to \nu W$, $m_{e^*} > 44.6$ GeV.

[89] ACKERSTAFF 97 also obtain limit from charged current decay mode $e^* \to \nu W$, $m_{\nu_e^*} > 77.1$ GeV.

[90] From e^+e^- collisions at $\sqrt{s}$= 130–136 GeV.

[91] From e^+e^- collisions at $\sqrt{s}$= 130–140 GeV.

[92] BARDADIN-OTWINOWSKA 92 limit is independent of decay modes. Based on $\Delta\Gamma(Z)$<36 MeV.

[93] Limit is independent of e^* decay mode.

[94] ADEVA 90F is superseded by ADRIANI 93M.

[95] Superseded by DECAMP 92.

[96] ABE 88B limits assume $e^+e^- \to e^{*+}e^{*-}$ with one photon exchange only and $e^* \to e\gamma$ giving $ee\gamma\gamma$.

Limits for Excited e (e^*) from Single Production

These limits are from $e^+e^- \to e^*e$, $W \to e^*\nu$, or $ep \to e^*X$ and depend on transition magnetic coupling between e and e^*. All limits assume $e^* \to e\gamma$ decay except as noted. Limits from LEP, UA2, and H1 are for chiral coupling, whereas all other limits are for nonchiral coupling, $\eta_L = \eta_R = 1$. In most papers, the limit is expressed in the form of an excluded region in the $\lambda - m_{e^*}$ plane. See the original papers.

For limits prior to 1987, see our 1992 edition (Physical Review **D45,** 1 June, Part II (1992)).

[97] ADLOFF 02B search for single e^* production in ep collisions with the decays $e^* \to e\gamma$, eZ, νW. $f = f' = \Lambda/m_{e^*}$ is assumed for the e^* coupling. See their Fig. 3 for the exclusion plot in the mass-coupling plane.

[98] ACHARD 03B result is from e^+e^- collisions at $\sqrt{s} = 189$–209 GeV. See their Fig. 4 for the exclusion plot in the mass-coupling plane.

[99] ABBIENDI 02G result is from e^+e^- collisions at $\sqrt{s} = 183$–209 GeV. $f = f' = \Lambda/m_{e^*}$ is assumed for e^* coupling. See their Fig. 4c for the exclusion limit in the mass-coupling plane.

[100] CHEKANOV 02D search for single e^* production in ep collisions with the decays $e^* \to e\gamma$, eZ, νW. $f = f' = \Lambda/m_{e^*}$ is assumed for the e^* coupling. See their Fig. 5a for the exclusion plot in the mass-coupling plane.

[101] ACCIARRI 01D result is from e^+e^- collisions at $\sqrt{s} = 192$–202 GeV. $f = f' = \Lambda/m_{e^*}$ is assumed for the e^* coupling. See their Fig. 4 for limits in the mass-coupling plane.

[102] ABBIENDI 00I result is from e^+e^- collisions at $\sqrt{s}$=161–183 GeV. See their Fig. 7 for limits in mass-coupling plane.

[103] ACCIARRI 00E result is from e^+e^- collisions at $\sqrt{s}$=189 GeV. See their Fig. 3 for limits in mass-coupling plane.

[104] ADLOFF 00E search for single e^* production in ep collisions with the decays $e^* \to e\gamma$, eZ, νW. $f = f' = \Lambda/m_{e^*}$ is assumed for the e^* coupling. See their Fig. 9 for the exclusion plot in the mass-coupling plane.

[105] ABREU 99O result is from e^+e^- collisions at $\sqrt{s}$= 183 GeV. See their Figs. 4 and 5 for the exclusion limit in the mass-coupling plane.

[106] ACCIARRI 98T search for single e^* production in quasi-real Compton scattering. The limit is for $|\lambda| > 1.0 \times 10^{-1}$ and non-chiral coupling of e^*. See their Fig. 7 for the exclusion plot in the mass-coupling plane.

[107] ACKERSTAFF 98C from e^+e^- collisions at $\sqrt{s}$=170–172 GeV. See their Fig. 11 for the exclusion limit in the mass-coupling plane.

[108] BARATE 98U is from e^+e^- collision at $\sqrt{s} = M_Z$. See their Fig. 12 for limits in mass-coupling plane

[109] From e^+e^- collisions at $\sqrt{s}$= 161 GeV.

[110] See Fig. 4a and Fig. 5a of ABREU 97B for the exclusion limit in the mass-coupling plane.

[111] See Fig. 2 and Fig. 3 of ACCIARRI 97G for the exclusion limit in the mass-coupling plane.

[112] ACKERSTAFF 97 result is from e^+e^- collisions at $\sqrt{s}$= 161 GeV. See their Fig. 3 for the exclusion limit in the mass-coupling plane.

[113] ADLOFF 97 search for single e^* production in ep collisions with the decays $e^* \to e\gamma$, eZ, νW. See their Fig. 4 for the rejection limits on the product of the production cross section and the branching ratio into a specific decay channel.

[114] BREITWEG 97C search for single e^* production in ep collisions with the decays $e^* \to e\gamma$, eZ, νW. $f = f' = 2\Lambda/m_{e^*}$ is assumed for the e^* coupling. See their Fig. 9 for the exclusion plot in the mass-coupling plane.

[115] ABREU 96K result is from e^+e^- collisions at $\sqrt{s}$= 130–136 GeV. See their Fig. 4 for the exclusion limit in the mass-coupling plane.

[116] ACCIARRI 96D result is from e^+e^- collisions at $\sqrt{s}$= 130–140 GeV. See their Fig. 2 for the exclusion limit in the mass-coupling plane.

[117] ALEXANDER 96Q result is from e^+e^- collisions at $\sqrt{s}$= 130–140 GeV. See their Fig. 3a for the exclusion limit in the mass-coupling plane.

[118] BUSKULIC 96W result is from e^+e^- collisions at $\sqrt{s}$= 130–140 GeV. See their Fig. 3 for the exclusion limit in the mass-coupling plane.

[119] DERRICK 95B search for single e^* production via $e^*e\gamma$ coupling in ep collisions with the decays $e^* \to e\gamma$, eZ, νW. See their Fig. 13 for the exclusion plot in the m_{e^*}–λ_γ plane.

[120] ABT 93 search for single e^* production via $e^*e\gamma$ coupling in ep collisions with the decays $e^* \to e\gamma$, eZ, νW. See their Fig. 4 for exclusion plot in the m_{e^*}–λ_γ plane.

[121] DERRICK 93B search for single e^* production via $e^*e\gamma$ coupling in ep collisions with the decays $e^* \to e\gamma$, eZ, νW. See their Fig. 3 for exclusion plot in the m_{e^*}–λ_γ plane.

[122] Superseded by ADRIANI 93M.

[123] Superseded by DECAMP 92.

[124] ABE 88B limits use $e^+e^- \to ee^*$ where t-channel photon exchange dominates giving $e\gamma(e)$ (quasi-real compton scattering).

[125] ANSARI 87D is at E_{cm} = 546–630 GeV.

Limits for Excited e (e^*) from $e^+e^- \to \gamma\gamma$

These limits are derived from indirect effects due to e^* exchange in the t channel and depend on transition magnetic coupling between e and e^*. All limits are for $\lambda_\gamma = 1$. All limits except ABE 89J and ACHARD 02D are for nonchiral coupling with $\eta_L = \eta_R = 1$. We choose the chiral coupling limit as the best limit and list it in the Summary Table.

For limits prior to 1987, see our 1992 edition (Physical Review **D45**, 1 June, Part II (1992)).

[126] ACCIARRI 00G also obtain a limit on e^* with chiral coupling, $m_{e^*} > 213$ GeV.

[127] BARATE 98U is from e^+e^- collision at $\sqrt{s} = M_Z$. See their Fig. 5 for limits in mass-coupling plane

[128] ACCIARRI 97W also obtain a limit on e^* with chiral coupling, $m_{e^*} > 157$ GeV (95%CL).

[129] BUSKULIC 93Q obtain $\Lambda^+ > 121$ GeV (95%CL) from ALEPH experiment and $\Lambda^+ > 135$ GeV from combined TRISTAN and ALEPH data. These limits roughly correspond to limits on m_{e^*}.

[130] ADRIANI 92B superseded by ACCIARRI 95G.

[131] BARDADIN-OTWINOWSKA 92 limit from fit to the combined data of DECAMP 92, ABREU 91E, ADEVA 90K, AKRAWY 91F.

[132] SHIMOZAWA 92 fit the data to the limiting form of the cross section with $m_{e^*} \gg E_{cm}$ and obtain $m_{e^*} > 168$ GeV at 95%CL. Use of the full form would reduce this limit by a few GeV. The statistically unexpected large value is due to fluctuation in the data.

[133] The ABE 89J limit assumes chiral coupling. This corresponds to $\lambda_\gamma = 0.7$ for nonchiral coupling.

Indirect Limits for Excited e (e^*)

These limits make use of loop effects involving e^* and are therefore subject to theoretical uncertainty.

VALUE (GeV)	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
	[134] DORENBOS...	89	CHRM	$\overline{\nu}_\mu e \to \overline{\nu}_\mu e$ and $\nu_\mu e \to \nu_\mu e$
	[135] GRIFOLS	86	THEO	$\nu_\mu e \to \nu_\mu e$
	[136] RENARD	82	THEO	$g-2$ of electron

[134] DORENBOSCH 89 obtain the limit $\lambda_\gamma^2 \Lambda_{\rm cut}^2 / m_{e^*}^2 < 2.6$ (95% CL), where $\Lambda_{\rm cut}$ is the cutoff scale, based on the one-loop calculation by GRIFOLS 86. If one assumes that $\Lambda_{\rm cut} = 1$ TeV and $\lambda_\gamma = 1$, one obtains $m_{e^*} > 620$ GeV. However, one generally expects $\lambda_\gamma \approx m_{e^*}/\Lambda_{\rm cut}$ in composite models.

[135] GRIFOLS 86 uses $\nu_\mu e \to \nu_\mu e$ and $\overline{\nu}_\mu e \to \overline{\nu}_\mu e$ data from CHARM Collaboration to derive mass limits which depend on the scale of compositeness.

[136] RENARD 82 derived from $g-2$ data limits on mass and couplings of e^* and μ^*. See figures 2 and 3 of the paper.

MASS LIMITS for Excited μ (μ^*)

Limits for Excited μ (μ^*) from Pair Production

These limits are obtained from $e^+e^- \to \mu^{*+}\mu^{*-}$ and thus rely only on the (electroweak) charge of μ^*. Form factor effects are ignored unless noted. For the case of limits from Z decay, the μ^* coupling is assumed to be of sequential type. All limits assume a dominant $\mu^* \to \mu\gamma$ decay except the limits from $\Gamma(Z)$.

For limits prior to 1987, see our 1992 edition (Physical Review **D45,** 1 June, Part II (1992)).

[137] From e^+e^- collisions at $\sqrt{s} = 183$–209 GeV. $f = f'$ is assumed.

[138] From e^+e^- collisions at $\sqrt{s} = 189$–209 GeV. $f = f'$ is assumed. ACHARD 03B also obtain limit for $f = -f'$: $m_{\mu^*} > 96.6$ GeV.

[139] From e^+e^- collisions at $\sqrt{s} = 192$–202 GeV. $f=f'$ is assumed. ACCIARRI 01D also obtain limit for $f=-f'$: $m_{\mu^*} > 93.4$ GeV.

[140] From e^+e^- collisions at $\sqrt{s}$=161–183 GeV. $f=f'$ is assumed. ABBIENDI 00I also obtain limit for $f=-f'$ ($\mu^* \to \nu W$): $m_{\mu^*} > 86.0$ GeV.

[141] From e^+e^- collisions at $\sqrt{s}$=189 GeV. $f=f'$ is assumed. ACCIARRI 00E also obtain limit for $f=-f'$ ($\mu^* \to \nu W$): $m_{\mu^*} > 92.6$ GeV.

[142] From e^+e^- collisions at $\sqrt{s}$= 183 GeV. $f=f'$ is assumed. ABREU 99O also obtain limit for $f=-f'$ ($\mu^* \to \nu W$): $m_{\mu^*} > 81.3$ GeV.

[143] From e^+e^- collisions at $\sqrt{s}$=170–172 GeV. ACKERSTAFF 98C also obtain limit from $\mu^* \to \nu W$ decay mode: $m_{\mu^*} > 81.3$ GeV.

[144] BARATE 98U obtain limits on the form factor. See their Fig. 14 for limits in mass-form factor plane.

[145] From e^+e^- collisions at $\sqrt{s}$= 161 GeV.

[146] ABREU 97B also obtain limit from charged current decay mode $\mu^* \to \nu W$, $m_{\mu^*} > 70.9$ GeV.

[147] ABREU 97B also obtain limit from charged current decay mode $\mu^* \to \nu W$, $m_{\mu^*} > 44.6$ GeV.

[148] ACKERSTAFF 97 also obtain limit from charged current decay mode $\mu^* \to \nu W$, $m_{\nu_\mu^*} > 77.1$ GeV.

[149] From e^+e^- collisions at $\sqrt{s}$= 130–136 GeV.

[150] From e^+e^- collisions at $\sqrt{s}$= 130–140 GeV.

[151] BARDADIN-OTWINOWSKA 92 limit is independent of decay modes. Based on $\Delta\Gamma(Z)$<36 MeV.

[152] Limit is independent of μ^* decay mode.

[153] Superseded by ADRIANI 93M.

[154] Superseded by DECAMP 92.

Limits for Excited μ (μ^*) from Single Production

These limits are from $e^+e^- \to \mu^*\mu$ and depend on transition magnetic coupling between μ and μ^*. All limits assume $\mu^* \to \mu\gamma$ decay. Limits from LEP are for chiral coupling, whereas all other limits are for nonchiral coupling, $\eta_L = \eta_R = 1$. In most papers, the limit is expressed in the form of an excluded region in the λ–m_{μ^*} plane. See the original papers.

For limits prior to 1987, see our 1992 edition (Physical Review **D45**, 1 June, Part II (1992)).

[174] From e^+e^- collisions at $\sqrt{s} = 183$–209 GeV. $f = f'$ is assumed.

[175] From e^+e^- collisions at $\sqrt{s} = 189$–209 GeV. $f = f'$ is assumed. ACHARD 03B also obtain limit for $f = -f'$: $m_{\tau^*} > 96.6$ GeV.

[176] From e^+e^- collisions at $\sqrt{s} = 192$–202 GeV. f=f' is assumed. ACCIARRI 01D also obtain limit for f=$-f'$: $m_{\tau^*} > 93.4$ GeV.

[177] From e^+e^- collisions at $\sqrt{s}$=161–183 GeV. f=f' is assumed. ABBIENDI 00I also obtain limit for f=$-f'$ ($\tau^* \to \nu W$): $m_{\tau^*} > 86.0$ GeV.

[178] From e^+e^- collisions at $\sqrt{s}$=189 GeV. f=f' is assumed. ACCIARRI 00E also obtain limit for f=$-f'$ ($\tau^* \to \nu W$): $m_{\tau^*} > 92.6$ GeV.

[179] From e^+e^- collisions at $\sqrt{s}$= 183 GeV. f=f' is assumed. ABREU 99O also obtain limit for f=$-f'$ ($\tau^* \to \nu W$): $m_{\tau^*} > 81.3$ GeV.

[180] From e^+e^- collisions at $\sqrt{s}$=170–172 GeV. ACKERSTAFF 98C also obtain limit from $\tau^* \to \nu W$ decay mode: $m_{\tau^*} > 81.3$ GeV.

[181] BARATE 98U obtain limits on the form factor. See their Fig. 14 for limits in mass-form factor plane.

[182] From e^+e^- collisions at $\sqrt{s}$= 161 GeV.

[183] ABREU 97B also obtain limit from charged current decay mode $\tau^* \to \nu W$, $m_{\tau^*} > 70.9$ GeV.

[184] ABREU 97B also obtain limit from charged current decay mode $\tau^* \to \nu W$, $m_{\tau^*} > 44.6$ GeV.

[185] ACKERSTAFF 97 also obtain limit from charged current decay mode $\tau^* \to \nu W$, $m_{\nu^*_\tau} > 77.1$ GeV.

[186] From e^+e^- collisions at $\sqrt{s}$= 130–136 GeV.

[187] From e^+e^- collisions at $\sqrt{s}$= 130–140 GeV.

[188] BARDADIN-OTWINOWSKA 92 limit is independent of decay modes. Based on $\Delta\Gamma(Z)$<36 MeV.

[189] Limit is independent of τ^* decay mode.

[190] Superseded by ADRIANI 93M.

[191] Superseded by DECAMP 92.

Limits for Excited τ (τ^*) from Single Production

These limits are from $e^+e^- \to \tau^*\tau$ and depend on transition magnetic coupling between τ and τ^*. All limits assume $\tau^* \to \tau\gamma$ decay. Limits from LEP are for chiral coupling, whereas all other limits are for nonchiral coupling, $\eta_L = \eta_R = 1$. In most papers, the limit is expressed in the form of an excluded region in the λ–m_{τ^*} plane. See the original papers.

[192] ABBIENDI 02G result is from e^+e^- collisions at $\sqrt{s} = 183$–209 GeV. $f = f' = \Lambda/m_{\tau^*}$ is assumed for τ^* coupling. See their Fig. 4c for the exclusion limit in the mass-coupling plane.

[193] ACHARD 03B result is from e^+e^- collisions at $\sqrt{s} = 189$–209 GeV. $f = f' = \Lambda/m_{\tau^*}$ is assumed. See their Fig. 4 for the exclusion plot in the mass-coupling plane.

[194] ACCIARRI 01D result is from e^+e^- collisions at $\sqrt{s} = 192$–202 GeV. f=f'=Λ/m_{τ^*} is assumed for the τ^* coupling. See their Fig. 4 for limits in the mass-coupling plane.

[195] ABBIENDI 00I result is from e^+e^- collisions at $\sqrt{s}$=161–183 GeV. See their Fig. 7 for limits in mass-coupling plane.

[196] ACCIARRI 00E result is from e^+e^- collisions at $\sqrt{s}$=189 GeV. See their Fig. 3 for limits in mass-coupling plane.

[197] ABREU 99O result is from e^+e^- collisions at $\sqrt{s}$= 183 GeV. See their Figs. 4 and 5 for the exclusion limit in the mass-coupling plane.

[198] ACKERSTAFF 98C from e^+e^- collisions at $\sqrt{s}$=170–172 GeV. See their Fig. 11 for the exclusion limit in the mass-coupling plane.

[199] BARATE 98U obtain limits on the $Z\tau\tau^*$ coupling. See their Fig. 12 for limits in mass-coupling plane

[200] From e^+e^- collisions at $\sqrt{s}$= 161 GeV.

[201] See Fig. 4a and Fig. 5a of ABREU 97B for the exclusion limit in the mass-coupling plane.

[202] See Fig. 2 and Fig. 3 of ACCIARRI 97G for the exclusion limit in the mass-coupling plane.

[203] ACKERSTAFF 97 result is from e^+e^- collisions at $\sqrt{s}$= 161 GeV. See their Fig. 3 for the exclusion limit in the mass-coupling plane.

[204] ABREU 96K result is from e^+e^- collisions at $\sqrt{s}$= 130–136 GeV. See their Fig. 4 for the exclusion limit in the mass-coupling plane.

[205] ACCIARRI 96D result is from e^+e^- collisions at $\sqrt{s}$= 130–140 GeV. See their Fig. 2 for the exclusion limit in the mass-coupling plane.

[206] ALEXANDER 96Q result is from e^+e^- collisions at $\sqrt{s}$= 130–140 GeV. See their Fig. 3a for the exclusion limit in the mass-coupling plane.

[207] BUSKULIC 96W result is from e^+e^- collisions at $\sqrt{s}$= 130–140 GeV. See their Fig. 3 for the exclusion limit in the mass-coupling plane.

[208] Superseded by ADRIANI 93M.

[209] Superseded by DECAMP 92.

[210] BARTEL 86 is at E_{cm} = 30–46.78 GeV.

[211] BEHREND 86 limit is at E_{cm} = 33–46.8 GeV.

MASS LIMITS for Excited Neutrino (ν^*)

Limits for Excited ν (ν^*) from Pair Production

These limits are obtained from $e^+e^- \to \nu^*\nu^*$ and thus rely only on the (electroweak) charge of ν^*. Form factor effects are ignored unless noted. The ν^* coupling is assumed to be of sequential type unless otherwise noted. All limits assume a dominant $\nu^* \to \nu\gamma$ decay except the limits from $\Gamma(Z)$.

[212] From e^+e^- collisions at $\sqrt{s} = 189$–209 GeV. $f = -f'$ is assumed. ACHARD 03B also obtain limit for $f = f'$: $m_{\nu_e^*} > 101.7$ GeV, $m_{\nu_\mu^*} > 101.8$ GeV, and $m_{\nu_\tau^*} > 92.9$ GeV. See their Fig. 4 for the exclusion plot in the mass-coupling plane.

[213] From e^+e^- collisions at $\sqrt{s} = 192$–202 GeV. f=f' is assumed. ACCIARRI 01D also obtain limit for f=$-f'$: $m_{\nu_e^*} > 99.1$ GeV, $m_{\nu_\mu^*} > 99.3$ GeV, $m_{\nu_\tau^*} > 90.5$ GeV.

[214] From e^+e^- collisions at $\sqrt{s}$=161–183 GeV. f=$-f'$ (photonic decay) is assumed. ABBIENDI 00I also obtain limit for f=f' ($\nu^* \to \ell W$): $m_{\nu_e^*} > 91.1$ GeV, $m_{\nu_\mu^*} > 91.1$ GeV, $m_{\nu_\tau^*} > 83.1$ GeV.

[215] From e^+e^- collisions at $\sqrt{s}$= 189 GeV. ABBIENDI,G 00D obtain limit on $\sigma(e^+e^- \to \nu^*\nu^*)B(\nu^* \to \nu\gamma)^2$. See their Fig. 14. The limit ranges from 50 to 80 fb for $\sqrt{s}/2$= 95 GeV> m_{ν^*} >45 GeV.

[216] From e^+e^- collisions at $\sqrt{s}$=189 GeV. f=$-f'$ (photonic decay) is assumed. ACCIARRI 00E also obtain limit for f=f' ($\nu^* \to \ell W$): $m_{\nu_e^*} > 93.9$ GeV, $m_{\nu_\mu^*} > 94.0$ GeV, $m_{\nu_\tau^*} > 91.5$ GeV.

[217] From e^+e^- collisions at $\sqrt{s}$= 130–183 GeV, ABBIENDI 99F obtain limit on $\sigma(e^+e^- \to \nu^*\nu^*)$ B($\nu^* \to \nu\gamma)^2$. See their Fig. 13. The limit ranges from 0.094 to 0.14 pb for $\sqrt{s}/2 > m_{\nu^*} >$ 45 GeV.

[218] From e^+e^- collisions at $\sqrt{s}$= 183 GeV. f=$-f'$ is assumed. ABREU 99O also obtain limit for f=f': $m_{\nu_{e^*}} > 87.3$ GeV, $m_{\nu_{\mu^*}} > 88.0$ GeV, $m_{\nu_{\tau^*}} > 81.0$ GeV.

[219] From e^+e^- collisions at $\sqrt{s}$=170–172 GeV. ACKERSTAFF 98C also obtain limit from charged decay modes: $m_{\nu_e^*} > 84.1$ GeV, $m_{\nu_\mu^*} > 83.9$ GeV, and $m_{\nu_\tau^*} > 79.4$ GeV.

[220] BARATE 98U obtain limits on the form factor. See their Fig. 14 for limits in mass-form factor plane.

[221] From e^+e^- collisions at $\sqrt{s}$= 161 GeV.

[222] ABREU 97B also obtain limits from charged current decay modes, $m_{\nu^*} > 56.4$ GeV.

[223] ABREU 97B also obtain limits from charged current decay modes, $m_{\nu^*} > 44.9$ GeV.

[224] ACCIARRI 97G also obtain limits from charged current decay mode $\nu_e^* \to eW$, $m_{\nu^*} >$ 64.5 GeV.

[225] ACKERSTAFF 97 also obtain limits from charged current decay modes $m_{\nu_e^*} > 78.3$ GeV, $m_{\nu_\mu^*} > 78.9$ GeV, $m_{\nu_\tau^*} > 76.2$ GeV.

[226] From e^+e^- collisions at $\sqrt{s}$= 130–140 GeV.

[227] ACCIARRI 96D also obtain limit from $\nu^* \to eW$ decay mode: $m_{\nu^*} > 57.3$ GeV.

[228] From e^+e^- collisions at $\sqrt{s}$= 130–136 GeV.

[229] ALEXANDER 96Q also obtain limits from charged current decay modes: $m_{\nu_e^*} > 66.2$ GeV, $m_{\nu_\mu^*} > 66.5$ GeV, $m_{\nu_\tau^*} > 64.7$ GeV.

[230] BARDADIN-OTWINOWSKA 92 limit is for Dirac ν^*. Based on $\Delta\Gamma(Z)$<36 MeV. The limit is 36.4 GeV for Majorana ν^*, 45.4 GeV for homodoublet ν^*.

[231] Limit is based on B($Z \to \nu^*\overline{\nu}^*$)×B($\nu^* \to \nu\gamma)^2 < 5 \times 10^{-5}$ (95%CL) assuming Dirac ν^*, B($\nu^* \to \nu\gamma$) = 1.

[232] Limit is for Dirac ν^*. The limit is 34.6 GeV for Majorana ν^*, 45.4 GeV for homodoublet ν^*.

[233] DECAMP 90O limit is from excess $\Delta\Gamma(Z) < 89$ MeV. The above value is for Dirac ν^*; 26.6 GeV for Majorana ν^*; 44.8 GeV for homodoublet ν^*.

[234] Superseded by DECAMP 92.

[235] DECAMP 90O limit based on B($Z \to \nu^*\nu^*$)·B($\nu^* \to \nu\gamma)^2 < 7 \times 10^{-5}$ (95%CL), assuming Dirac ν^*, B($\nu^* \to \nu\gamma$) = 1.

Limits for Excited ν (ν^*) from Single Production

These limits are from $e^+e^- \to \nu\nu^*$, $Z \to \nu\nu^*$, or $ep \to \nu^*X$ and depend on transition magnetic coupling between ν/e and ν^*. Assumptions about ν^* decay mode are given in footnotes.

[236] ACHARD 03B result is from e^+e^- collisions at $\sqrt{s} = 189$–209 GeV. The quoted limit is for ν_e^*. $f = -f' = \Lambda/m_{\nu^*}$ is assumed. See their Fig. 4 for the exclusion plot in the mass-coupling plane.

[237] ADLOFF 02 search for single ν^* production in ep collisions with the decays $\nu^* \to \nu\gamma$, νZ, eW. The quoted limit assumes $f = -f' = \Lambda/m_{\nu^*}$. See their Fig. 1 for the exclusion plots in the mass-coupling plane.

[238] CHEKANOV 02D search for single ν^* production in ep collisions with the decays $\nu^* \to \nu\gamma$, νZ, eW. $f = -f' = \Lambda/m_{\nu^*}$ is assumed for the e^* coupling. CHEKANOV 02D also obtain limit for $f = f' = \Lambda/m_{\nu^*}$: $m_{\nu^*} >$135 GeV. See their Fig. 5c and Fig. 5d for the exclusion plot in the mass-coupling plane.

[239] ACCIARRI 01D search for $\nu\nu^*$ production in e^+e^- collisions at $\sqrt{s} = 192$–202 GeV with decays $\nu^* \to \nu\gamma$, $\nu^* \to eW$. f=$-f'$=Λ/m_{ν^*} is assumed for the ν^* coupling. See their Fig. 4 for limits in the mass-coupling plane.

[240] ABBIENDI 00I result is from e^+e^- collisions at $\sqrt{s}$=161–183 GeV. See their Fig. 7 for limits in mass-coupling plane.

[241] From e^+e^- collisions at $\sqrt{s}$= 189 GeV. ABBIENDI,G 00D obtain limit on $\sigma(e^+e^- \to \nu^*\nu^*)$B($\nu^* \to \nu\gamma)^2$. See their Fig. 11.

[242] ACCIARRI 00E result is from e^+e^- collisions at $\sqrt{s}$=189 GeV. See their Fig. 3 for limits in mass-coupling plane.

[243] ADLOFF 00E search for single ν^* production in ep collisions with the decays $\nu^* \to \nu\gamma$, νZ, eW. The quoted limit assumes f=$-f'$=Λ/m_{ν^*}. See their Fig. 10 for the exclusion plot in the mass-coupling plane.

[244] From e^+e^- collisions at $\sqrt{s}$= 130–183 GeV, ABBIENDI 99F obtain limit on $\sigma(e^+e^- \to \nu\nu^*)$ B($\nu^* \to \nu\gamma$). See their Fig. 8.

[245] ABREU 99O result is from e^+e^- collisions at $\sqrt{s}$= 183 GeV. See their Figs. 4 and 5 for the exclusion limit in the mass-coupling plane.

[246] ACKERSTAFF 98C from e^+e^- collisions at $\sqrt{s}$=170–172 GeV. See their Fig. 11 for the exclusion limit in the mass-coupling plane.

[247] BARATE 98U obtain limits on the $Z\nu\nu^*$ coupling. See their Fig. 13 for limits in mass-coupling plane

[248] From e^+e^- collisions at $\sqrt{s}$= 161 GeV.

[249] See Fig. 4b and Fig. 5b of ABREU 97B for the exclusion limit in the mass-coupling plane.

[250] ABREU 97I limit is from $Z \to \nu\nu^*$. See their Fig. 12 for the exclusion limit in the mass-coupling plane.

[251] ABREU 97J limit is from $Z \to \nu\nu^*$. See their Fig. 5 for the exclusion limit in the mass-coupling plane.

[252] See Fig. 2 and Fig. 3 of ACCIARRI 97G for the exclusion limit in the mass-coupling plane.

[253] ACKERSTAFF 97 result is from e^+e^- collisions at $\sqrt{s}$= 161 GeV, for homodoublet ν^*. See their Fig. 3 for the exclusion limit in the mass-coupling plane.

[254] ADLOFF 97 search for single e^* production in ep collisions with the decays $e^* \to e\gamma$, eZ, νW. See their Fig. 4 for the rejection limits on the product of the production cross section and the branching ratio.

[255] BREITWEG 97C search for single ν^* production in ep collisions with the decay $\nu^* \to \nu\gamma$. f=$-f'$=$2\Lambda/m_{\nu^*}$ is assumed for the ν^* coupling. See their Fig. 10 for the exclusion plot in the mass-coupling plane.

[256] ACCIARRI 96D result is from e^+e^- collisions at $\sqrt{s}$= 130–140 GeV. See their Fig. 2 for the exclusion limit in the mass-coupling plane.

[257] ALEXANDER 96Q result is from e^+e^- collisions at $\sqrt{s}$= 130–140 GeV for homodoublet ν^*. See their Fig. 3b and Fig. 3c for the exclusion limit in the mass-coupling plane.

[258] BUSKULIC 96W result is from e^+e^- collisions at $\sqrt{s}$= 130–140 GeV. See their Fig. 4 for the exclusion limit in the mass-coupling plane.

[259] DERRICK 95B search for single ν^* production via ν^*eW coupling in ep collisions with the decays $\nu^* \to \nu\gamma$, νZ, eW. See their Fig. 14 for the exclusion plot in the m_{ν^*}–$\lambda\gamma$ plane.

[260] ABT 93 search for single ν^* production via ν^*eW coupling in ep collisions with the decays $\nu^* \to \nu\gamma$, νZ, eW. See their Fig. 4 for exclusion plot in the m_{ν^*}–λ_W plane.

[261] See Fig. 5 of BARDADIN-OTWINOWSKA 92 for combined limit of ADEVA 90O, DECAMP 90O, and DECAMP 92.

[262] DECAMP 92 limit is based on B($Z \to \nu^*\overline{\nu}$)×B($\nu^* \to \nu\gamma) < 2.7 \times 10^{-5}$ (95%CL) assuming Dirac ν^*, B($\nu^* \to \nu\gamma$) = 1.

[263] Limit is either for $\nu^* \to \nu\gamma$ or $\nu^* \to eW$.

[264] Superseded by ADRIANI 93M.

[265] DECAMP 90O limit based on B($Z \to \nu\nu^*$)·B($\nu^* \to \nu\gamma) < 6 \times 10^{-5}$ (95%CL), assuming B($\nu^* \to \nu\gamma$) = 1.

[266] Superseded by DECAMP 92.

MASS LIMITS for Excited q (q^*)

Limits for Excited q (q^*) from Pair Production

These limits are obtained from $e^+e^- \to q^*\overline{q}^*$ and thus rely only on the (electroweak) charge of the q^*. Form factor effects are ignored unless noted. Assumptions about the q^* decay are given in the comments and footnotes.

>23.2	95	[273] BEHREND	86C	CELL	$e(q^*) = 2/3$, $q^* \to q\gamma$

[267] ADRIANI 93M limit is valid for $B(q^* \to qg) > 0.25$ (0.17) for up (down) type.

[268] BARATE 98U obtain limits on the form factor. See their Fig. 16 for limits in mass-form factor plane.

[269] ADRIANI 92F search for $Z \to q^*\overline{q}^*$ followed with $q^* \to q\gamma$ decays and give the limit $\sigma_Z \cdot B(Z \to q^*\overline{q}^*) \cdot B^2(q^* \to q\gamma) < 2$ pb at 95%CL. Assuming five flavors of degenerate q^* of homodoublet type, $B(q^* \to q\gamma) < 4\%$ is obtained for $m_{q^*} < 45$ GeV.

[270] BARDADIN-OTWINOWSKA 92 limit based on $\Delta\Gamma(Z) < 36$ MeV.

[271] These limits are independent of decay modes.

[272] Limit is for $B(q^* \to qg) + B(q^* \to q\gamma) = 1$.

[273] BEHREND 86C search for $e^+e^- \to q^*\overline{q}^*$ for $m_{q^*} > 5$ GeV. But $m < 5$ GeV excluded by total hadronic cross section. The limits are for point-like photon couplings of excited quarks.

Limits for Excited q (q^*) from Single Production

These limits are from $e^+e^- \to q^*\overline{q}$ or $p\overline{p} \to q^*X$ and depend on transition magnetic couplings between q and q^*. Assumptions about q^* decay mode are given in the footnotes and comments.

[274] ABE 97G search for new particle decaying to dijets.

[275] ABE 95N assume a degenerate u^* and d^* with $f_s = f = f' = \Lambda/m_{q^*}$. See their Fig. 4 for the excluded region in $m_{q^*} - f$ plane.

[276] ALITTI 93 search for resonances in the two-jet invariant mass. The limit is for $f_s = f = f' = \Lambda/m_{q^*}$. u^* and d^* are assumed to be degenerate. If not, the limit for u^* (d^*) is 277 (247) GeV if $m_{d^*} \gg m_{u^*}$ ($m_{u^*} \gg m_{d^*}$).

[277] CHEKANOV 02D search for single q^* production in ep collisions with the decays $q^* \to q\gamma$, qZ, qW. $f_s = 0$ and $f = f' = \Lambda/m_{q^*}$ is assumed for the q^* coupling. See their Fig. 5b for the exclusion plot in the mass-coupling plane.

[278] ADLOFF 00E search for single q^* production in ep collisions with the decays $q^* \to q\gamma$, qZ, qW. $f_s = 0$ and $f = f' = \Lambda/m_{q^*}$ is assumed for the q^* coupling. See their Fig. 11 for the exclusion plot in the mass-coupling plane.

[279] ABREU 99O result is from e^+e^- collisions at $\sqrt{s} = 183$ GeV. See their Fig. 6 for the exclusion limit in the mass-coupling plane.

[280] BARATE 98U obtain limits on the Zqq^* coupling. See their Fig. 16 for limits in mass-coupling plane

[281] ADLOFF 97 search for single q^* production in ep collisions with the decay $q^* \to q\gamma$. See their Fig. 6 for the rejection limits on the product of the production cross section and the branching ratio.

[282] BREITWEG 97C search for single q^* production in ep collisions with the decays $q^* \to q\gamma$, qW. $f_s = 0$, and $f = -f' = 2\Lambda/m_{q^*}$ is assumed for the q^* coupling. See their Fig. 11 for the exclusion plot in the mass-coupling plane.

[283] DERRICK 95B search for single q^* production via $q^*q\gamma$ coupling in ep collisions with the decays $q^* \to qW$, qZ, qg, $q\gamma$. See their Fig. 15 for the exclusion plot in the $m_{q^*} - \lambda\gamma$ plane.

[284] ABE 94 search for resonances in jet-γ and jet-W invariant mass in $p\overline{p}$ collisions at $E_{cm} = 1.8$ TeV. The limit is for $f_s = f = f' = \Lambda/m_{q^*}$ and u^* and d^* are assumed to be degenerate. See their Fig. 4 for the excluded region in $m_{q^*} - f$ plane.

[285] Assumes $B(q^* \to qg) = 1$.

[286] ABREU 92D give $\sigma(e^+e^- \to Z \to q^*\overline{q}$ or $q\overline{q}^*) \times B(q^* \to q\gamma) < 15$ pb (95% CL) for $m_{q^*} < 80$ GeV.

[287] ADRIANI 92F search for $Z \to qq^*$ with $q^* \to q\gamma$ and give the limit $\sigma_Z \cdot B(Z \to qq^*) \cdot B(q^* \to q\gamma) < (2$–$10)$ pb (95%CL) for $m_{q^*} = (46$–$82)$ GeV.

[288] Assumes $B(q^* \to q\gamma) = 0.1$.

[289] ALBAJAR 89 give $\sigma(q^* \to W + \text{jet})/\sigma(W) < 0.019$ (90% CL) for $m_{q^*} > 220$ GeV.

[290] BEHREND 86C has $E_{cm} = 42.5$–46.8 GeV. See their Fig. 3 for excluded region in the $m_{q^*} - (\lambda_\gamma/m_{q^*})^2$ plane. The limit is for $\lambda_\gamma = 1$ with $\eta_L = \eta_R = 1$.

MASS LIMITS for Color Sextet Quarks (q_6)

VALUE (GeV)	CL%	DOCUMENT ID		TECN	COMMENT
>84	95	[291] ABE	89D	CDF	$p\overline{p} \to q_6\overline{q}_6$

[291] ABE 89D look for pair production of unit-charged particles which leave the detector before decaying. In the above limit the color sextet quark is assumed to fragment into a unit-charged or neutral hadron with equal probability and to have long enough lifetime not to decay within the detector. A limit of 121 GeV is obtained for a color decuplet.

MASS LIMITS for Color Octet Charged Leptons (ℓ_8)

$\lambda \equiv m_{\ell_8}/\Lambda$

VALUE (GeV)	CL%	DOCUMENT ID		TECN	COMMENT
>86	95	[292] ABE	89D	CDF	Stable ℓ_8: $p\overline{p} \to \ell_8\overline{\ell}_8$

none 5–23.2	95	[296] BARTEL	87B	JADE	μ_8: $e^+e^- \to \mu\mu +$ jets
		[297] BARTEL	85K	JADE	e_8: $e^+e^- \to gg$; R

[292] ABE 89D look for pair production of unit-charged particles which leave the detector before decaying. In the above limit the color octet lepton is assumed to fragment into a unit-charged or neutral hadron with equal probability and to have long enough lifetime not to decay within the detector. The limit improves to 99 GeV if it always fragments into a unit-charged hadron.

[293] ABT 93 search for e_8 production via e-gluon fusion in ep collisions with $e_8 \to eg$. See their Fig. 3 for exclusion plot in the m_{e_8}–Λ plane for $m_{e_8} = 35$–220 GeV.

[294] KIM 90 is at $E_{cm} = 50$–60.8 GeV. The same assumptions as in BARTEL 87B are used.

[295] KIM 90 result $(m_{e_8}\Lambda_M)^{1/2} > 178.4$ GeV (95%CL, $\alpha_s = 0.16$ used) is subject to the same restriction as for BARTEL 85K.

[296] BARTEL 87B is at $E_{cm} = 46.3$–46.78 GeV. The limits assume ℓ_8 pair production cross sections to be eight times larger than those of the corresponding heavy lepton pair production.

[297] In BARTEL 85K, R can be affected by $e^+e^- \to gg$ via e_q exchange. Their limit $m_{e_8} > 173$ GeV (CL=95%) at $\lambda = m_{e_8}/\Lambda_M = 1$ ($\eta_L = \eta_R = 1$) is not listed above because the cross section is sensitive to the product $\eta_L\eta_R$, which should be absent in ordinary theory with electronic chiral invariance.

MASS LIMITS for Color Octet Neutrinos (ν_8)

$\lambda \equiv m_{\ell_8}/\Lambda$

VALUE (GeV)	CL%	DOCUMENT ID		TECN	COMMENT
>110	90	[298] BARGER	89	RVUE	ν_8: $p\overline{p} \to \nu_8\overline{\nu}_8$
• • • We do not use the following data for averages, fits, limits, etc. • • •					
none 3.8–29.8	95	[299] KIM	90	AMY	ν_8: $e^+e^- \to$ acoplanar jets
none 9–21.9	95	[300] BARTEL	87B	JADE	ν_8: $e^+e^- \to$ acoplanar jets

[298] BARGER 89 used ABE 89B limit for events with large missing transverse momentum. Two-body decay $\nu_8 \to \nu g$ is assumed.

[299] KIM 90 is at $E_{cm} = 50$–60.8 GeV. The same assumptions as in BARTEL 87B are used.

[300] BARTEL 87B is at $E_{cm} = 46.3$–46.78 GeV. The limit assumes the ν_8 pair production cross section to be eight times larger than that of the corresponding heavy neutrino pair production. This assumption is not valid in general for the weak couplings, and the limit can be sensitive to its $SU(2)_L \times U(1)_Y$ quantum numbers.

MASS LIMITS for W_8 (Color Octet W Boson)

VALUE (GeV)	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
	[301] ALBAJAR	89	UA1	$p\overline{p} \rightarrow W_8 X$, $W_8 \rightarrow Wg$

[301] ALBAJAR 89 give $\sigma(W_8 \rightarrow W + \text{jet})/\sigma(W) < 0.019$ (90% CL) for $m_{W_8} > 220$ GeV.

Extra Dimensions

For explanation of terms used and discussion of significant model dependence of following limits, see the "Extra Dimensions Review." Limits are expressed in conventions of of Giudice, Rattazzi, and Wells as explained in the Review. Footnotes describe originally quoted limit. n indicates the number of extra dimensions.

Limits not encoded here are summarized in the "Extra Dimensions Review."

EXTRA DIMENSIONS

Written March 2002 by J. Hewett (SLAC) and J. March-Russell (CERN).

I. Introduction

The large separation between the weak scale $\sim 10^3$ GeV and the traditional scale of gravity—the Planck scale with $M_{\rm Pl} \sim 10^{19}$ GeV—is one of the most puzzling aspects of nature. The origin of this large ratio, as well as its stability under radiative corrections, demands explanation. This is known as the hierarchy problem. One theoretical means of solving this problem is to introduce Supersymmetry (see the "Note on Supersymmetry" in this Review). Alternatively one may hope to address the hierarchy by exploiting the geometry of space time. Specifically, recent theories involve the idea that the 3-spatial dimensions in which we live could be a 3-spatial-dimensional 'membrane' embedded in a much larger extra dimensional space, and that the hierarchy is generated by the geometry of the additional dimensions. Such ideas have led to extra dimensional theories which have verifiable consequences at the TeV scale.

See key on page 323

Our knowledge of the weak and strong forces extends down to scales of $\sim (100\ \text{GeV})^{-1}$ (or of order 10^{-15} mm). On the other hand, we have almost no knowledge of gravity at distances less than roughly a *millimeter*, as direct tests of the gravitational force at the smallest distances are based on torsion-balance experiments, which are mechanically limited. It is thus conceivable that gravity may behave quite differently from the 3-dimensional Newtonian theory at small distances.

This leads to the possibility that matter and non-gravitational forces are confined to our 3-dimensional subspace, whereas gravity may propagate throughout a higher dimensional volume. In this case, the gauge forces are trapped within our 3-dimensional space, unaware of the extra dimensions, and maintain their usual behavior. Gravity, on the other hand, would no longer follow the inverse-square force law at distances smaller than the size of the extra dimensions, as the gravitational equivalent of Gauss' Law mandates that the gravitational field spreads out into the full spatial volume.

Since Newton's Law must be reproduced at large distances, gravity must behave as if there were only three spatial dimensions for $r \gtrsim 1$ mm. This is achievable either by compactifying all the extra dimensions on circles, where the geometry of these dimensions is thus flat and the topology is that of a torus, or by using strong curvature effects in the extra dimensions. In the first case, Arkani-Hamed, Dimopoulos, and Dvali (ADD) [1,2] used this picture to generate the hierarchy by postulating a large volume for the extra dimensional space, building on earlier ideas in Refs. 3,4. In the latter case, the hierarchy can be established by a large curvature of the extra dimensions as demonstrated by Randall and Sundrum (RS) [5,6]. It is the relation of these models to the hierarchy which yields testable predictions at the TeV scale.

General Features of Models

More technically, our subspace of $(3+1)$ space-time dimensions is known as a '3-brane', where the terminology is derived from a generalization of a 2-dimensional membrane. This brane is embedded in a D-dimensional space-time, $D \equiv (3+\delta+1)$, known as the 'bulk'. It is usually assumed that all δ-dimensions transverse to the brane have a common size R. However, the brane can also have smaller extra dimensions associated with it, of size $r \ll R$, and through which it extends, leading to effects similar to a small finite thickness. The size and geometry of the bulk, as well as the types of particles which are allowed to propagate in the bulk and on the brane, vary between different models.

Upon compactification of the δ-additional dimensions, all fields which propagate in the bulk are Fourier expanded into a complete set of modes—the so-called Kaluza-Klein (KK) tower of states, with mode numbers $\vec{n} = (n_1, n_2, \ldots, n_\delta)$ labeling the KK excitations. Similar to a particle in a box, the momentum of the bulk field is quantized in the δ compactified dimensions, given by $\vec{p}_\delta{}^2 = \vec{n}\cdot\vec{n}/R^2$, where R is the compactification radius. From the 4d perspective of an observer on the brane, each allowed momentum in the compactified volume appears as a KK excitation of the bulk field with mass $m_{\vec{n}}^2 = \vec{p}_\delta{}^2$. This builds a KK tower of states where each KK excitation carries identical spin and gauge quantum numbers. Kaluza-Klein states are a generic feature of models with compactified dimensions. The above assumes that all additional dimensions are of the same size and are flat; in more complicated compactifications, the Fourier expansion must be generalized, and the mass formula no longer takes on the above simple form.

The many proposed scenarios may be divided into two categories, depending on whether they do or do not assume that the geometry of the full $(4+\delta)$-dimensional space time with metric G_{IJ} is of factorized form, where the $4d$ and δ-dimensional geometries are independent. In the factorized case, the metric can be put in the form

$$ds^2 = G_{IJ}dx^I dx^J = \eta_{\mu\nu}dx^\mu dx^\nu + h_{ij}(y)dy^i dy^j\ , \qquad (1)$$

where $I, J = (0, \ldots, 3+\delta)$, $\mu, \nu = (0, ..., 3)$ and $i, j = (1, \ldots, \delta)$. The metric h_{ij} for the extra dimensions is flat only if they are toroidal, as assumed in the ADD scenario. In general, however, the bulk geometry is curved, even in the factorized case, and this can have important consequences. In the non-factorizable case, where there is a function of y multiplying $\eta_{\mu\nu}dx^\mu dx^\nu$, the bulk geometry is automatically curved. This is sometimes referred to as a 'warped' geometry.

A further classification involves the field content assumed to be present in the bulk or confined to the brane. The latter may be accomplished via localization, where the field's wavefunction is narrowly peaked about the brane. The low-energy effective action for the bulk contains, at minimum, the higher-dimensional Einstein-Hilbert term

$$S = \int d^4x d^\delta y \sqrt{-\det G}\ \left\{\frac{\overline{M}_D^{(2+\delta)}}{2}\mathcal{R} + \ldots\right\} \qquad (2)$$

where $\mathcal{R}$ is the $(4+\delta)$-dimensional Ricci scalar. This expression defines the scale $\overline{M}_D$, which is the fundamental scale of the higher-dimensional theory, and is the analog of the 4-d reduced Planck mass, $\overline{M}_{\rm Pl} = 2.4 \times 10^{18}$ GeV. This theory is non-renormalizable, and thus, gravitational interactions grow with energy as $\sim (E/\overline{M}_D)^{(2+\delta)/2}$. Hence, as the energy in a process grows, the theory becomes strongly coupled, and $\overline{M}_D$ is the scale at which the low-energy description breaks down.

This bulk action is incomplete as it does not contain the dynamics that stabilize the extra dimensions at a given size [2,7,8]. This issue is very model-dependent and, with the exception of the warped scenario [5,9], no standard picture exists.

It is common practice to assume that the Standard Model (SM) fields are confined to the brane. A motivation for this assumption is that confinement of certain degrees of freedom (but not gravity in general) to branes is automatic [10] within string theory. However, if the extra dimensions are small enough, the SM fields are phenomenologically allowed to propagate in the

bulk, and this possibility allows for novel model-building techniques to address gauge coupling unification, Supersymmetry breaking, the neutrino mass spectrum, and the fermion mass hierarchy.

A general issue that can strongly affect the phenomenology of these scenarios is that branes can be of two types: 'rigid,' or flexible (see Refs. 7,8). If the brane is flexible, it can fluctuate in the extra dimensions, resulting in Nambu-Goldstone modes. These can have important phenomenological implications which are detailed below [11,12,13]. The other possibility is a rigid brane, which can be thought of as a boundary of the bulk space where gravity satisfies particular boundary conditions. In this case the Poincare invariance of the higher dimensional theory is *explicitly* broken and there are no Nambu-Goldstone modes. Due to the broken translational invariance, momentum in the transverse y^i directions is not conserved, and the production of a single bulk mode is allowed. Almost all studies to date consider this 'rigid brane' case.

II. Three scenarios

There are three principal scenarios with predictions at the TeV scale, each of which has a distinct phenomenology.

Large Extra Dimensions

In these theories [1,2], gravity alone propagates in the bulk, where it is assumed to become strong near the electroweak scale. Gauss' Law relates the (reduced) Planck scale of the effective 4d low-energy theory and the fundamental scale $\overline{M}_D$, through the volume of the compactified dimensions, V_δ, via

$$\overline{M}_{\rm Pl}^2 = V_\delta \overline{M}_D^{2+\delta} \ . \qquad (3)$$

(Here and below we use the conventions of [14].) $M_{\rm Pl}$ is thus no longer a fundamental scale as it is generated by the large volume of the higher dimensional space. If, following ADD, it is assumed that the extra dimensions are *flat*, and thus of toroidal form, then setting $\overline{M}_D \sim$ TeV to eliminate the hierarchy between $M_{\rm Pl}$ and the weak scale determines the compactification radius R of the extra dimensions. Under the simplifying assumption that all radii are of equal size, we can define $V_\delta = (2\pi R)^\delta$. R then ranges from a sub-millimeter to a few fermi for $\delta = 2$–6. The case of $\delta = 1$ is excluded as the corresponding dimension would directly alter Newton's law on solar-system scales. The large size of the additional dimensions forces the SM fields to be constrained to the brane. The bulk graviton expands into a KK tower of spin-2 states which have masses of $\sqrt{\vec{n}^2/R^2}$, where $\vec{n}$ labels the KK excitation level.

The interactions of the bulk graviton with matter and gauge fields are

$$S_{int} = -\frac{1}{\overline{M}_D^{\delta/2+1}} \int d^4x d^\delta y_i h_{AB}(x_\mu, y_i) T_{AB}(x_\mu, y_i) \ , \qquad (4)$$

where h_{AB} is the bulk graviton fluctuation, and T_{AB} is the symmetric conserved stress-energy tensor. Setting $T_{AB} = \eta_A^\mu \eta_B^\nu T_{\mu\nu} \delta(y_i)$ for fields on the brane, expanding h_{AB} into the KK tower, and integrating over $d^\delta y_i$ gives the interactions of the bulk KK gravitons with the SM fields on the brane. The Feynman rules governing these interactions are explicitly derived in Refs. 14,15. Each KK excitation state, G_n, couples universally to the Standard Model fields with a strength of $\overline{M}_{\rm Pl}^{-1}$. In addition, a scalar mode exists, which is the volume modulus or radion field representing the fluctuations of the compactification volume. This field couples to the trace of the stress-energy tensor. It is important to note that this description is an effective 4-dimensional theory, valid for energies below $\overline{M}_D$. The full theory above this scale is unknown.

TeV^{-1}-sized Extra Dimensions with SM Fields

The possibility of TeV^{-1}-sized extra dimensions arises in braneworld models [3]. It does not allow for a reformulation of the hierarchy problem. In this case, the Standard Model field content may propagate in the bulk. This allows for several model-building choices: (i) all, or only some, of the SM gauge fields are present in the bulk; (ii) the Higgs field(s) may be in the bulk or on the brane; (iii) the confinement of the SM fermions to the brane or to specific locales in the extra dimensions. If the Higgs field(s) propagate in the bulk, the vacuum expectation value (VEV) of the Higgs zero-mode, the $\vec{n} = 0$ KK state, generates spontaneous symmetry breaking. In this case, the gauge boson KK mass matrix is diagonal with the gauge excitation masses being given by $[M_0^2 + \vec{n} \cdot \vec{n}/R^2]^{1/2}$, where M_0 is the VEV-induced mass of the gauge zero-mode. However, if the Higgs is confined to the brane, its VEV induces off-diagonal elements in the mass matrix, generating mixing amongst the gauge KK states of order $(M_0 R)^2$. For the case of 1 extra dimension, the coupling strength of the bulk KK gauge states to the SM fermions is $\sqrt{2}g$, where g is the SM SU(2) coupling. The fermion fields may (a) be constrained to the rigid $(3+1)$-brane, in which case they are not directly affected by the extra dimensions; (b) be localized at specific points in the TeV^{-1} dimension, but not on a rigid brane. Here, the zero and excited-mode KK fermions obtain narrow Gaussian-like wave functions in the extra dimensions, with a width much smaller than R^{-1}. This possibility may suppress the rates for a number of dangerous processes such as proton decay [16]; (c) propagate in the bulk. This scenario is known as universal extra dimensions [17]. In this possibility, all fields propagate in the bulk, and thus, branes need not be present. $(4+\delta)$-dimensional momentum is then conserved at tree-level, and KK parity, $(-1)^n$, is conserved to all orders. The phenomenology is quite different for this brane-less theory.

Bulk KK gauge bosons within this context are also discussed in the section on Indirect Constraints on Kaluza-Klein Gauge Bosons in the Listings for "Searches for Heavy Bosons Other Than Higgs Bosons" in this *Review*.

Warped Extra Dimensions

In the simplest form of this scenario [5,6], known as RS1, gravity propagates in a 5d bulk of finite extent, with two rigid boundaries of dimensionality $(3+1)$. The Standard Model

fields are assumed to be constrained to one of these rigid $(3+1)$-branes. This configuration permits the metric

$$ds^2 = e^{-2ky}\eta_{\mu\nu}dx^\mu dx^\nu - dy^2\,, \qquad (5)$$

where the exponential function, or warp factor, multiplying the usual 4d Minkowski term, demonstrates the non-factorizable geometry, and $y \in [0, \pi R]$ is the coordinate of the extra dimension. Here, k describes the curvature scale, which together with $\overline{M}_D$ $(D = 5)$ is assumed [5,6] to be of order $\overline{M}_{\rm Pl}$, with

$$\overline{M}_{\rm Pl}^2 = \frac{\overline{M}_D^3}{k}(1 - e^{-2kR\pi})\,. \qquad (6)$$

Consistency of the low-energy description requires that the curvature be small, so $k/\overline{M}_{\rm Pl} \lesssim 0.1$ is assumed. Eq. (5) leads to the gravitational wavefunction being concentrated on the brane at $y = 0$. Moreover, the exponential dependence of proper length and energy scales with y implies that TeV scales are naturally realized and stabilized [9] on the second brane at $y = \pi R$, provided that $kR \simeq 10$. Therefore, the RS1 model [5] localizes the SM fields to this brane at $y = \pi R$. The scale $\Lambda_\pi = \overline{M}_{\rm Pl}e^{-kR\pi} \sim 1$ TeV describes the scale of all physical processes on this so-called 'TeV-brane' at $y = \pi R$. Note that since $kR \simeq 10$ and $k \sim 10^{18}$ GeV is assumed by Randall and Sundrum, this is *not* a model with a large extra dimension.

The 4d phenomenology is governed by the two parameters, Λ_π and $k/\overline{M}_{\rm Pl}$. The masses of the bulk graviton KK tower states on the TeV-brane are $m_n = x_n k e^{-kR\pi} = x_n \Lambda_\pi k/\overline{M}_{\rm Pl}$ with the x_n being the roots of the first-order Bessel function J_1. The KK states are thus not evenly spaced. For typical values of the parameters, the mass of the first graviton KK excitation is of order a TeV. The interactions of the bulk graviton KK tower with the SM fields are [18]

$$\Delta\mathcal{L} = -\frac{1}{M_{\rm Pl}}T^{\mu\nu}(x)h_{\mu\nu}^{(0)}(x) - \frac{1}{\Lambda_\pi}T^{\mu\nu}(x)\sum_{n=1}^{\infty}h_{\mu\nu}^{(n)}(x)\,. \qquad (7)$$

Experiments can determine or constrain the masses m_n and the coupling Λ_π. The couplings of the excitation states are inverse to TeV strength, which results in a different phenomenology than in the case of large extra dimensions.

Extensions of this basic model allow for the SM fields to propagate in the bulk [19,20] since R is small. In this case, the masses of the bulk fermion, gauge, and graviton KK states are related. A third parameter, associated with the fermion bulk mass, is introduced and governs the 4d phenomenology.

An alternate possibility is RS2 [6]; here the SM fields are assumed to live on the brane at $y = 0$, where the graviton zero mode is concentrated, and the second brane is taken off to infinity $R \to \infty$. In this case, there is *no* mass gap in the bulk KK modes, and their coupling to the SM fields on the $y = 0$ brane is much weaker than $1/M_{\rm Pl}$. The collider constraints are investigated in Ref. 21, and cosmological constraints in Ref. 22. Although this setup no longer provides a reformulation of the hierarchy problem, it allows for a modification of gravity, potentially giving signals in sub-mm gravitational force experiments.

III. Experimental constraints

Tests of the Gravitational Force Law

Deviations from the 4d inverse-square gravitational force law may be observable in the case of large flat (ADD) extra dimensions, or in the RS2 scenario. Gravity would obey Gauss' Law in $3+\delta$ spatial dimensions for distances $r < R$ with

$$V_{3+1+\delta}(r) = \frac{-1}{8\pi(2\pi)^\delta(\overline{M}_D)^{\delta+2}}\frac{m_1 m_2}{r^{\delta+1}}\,, \qquad (8)$$

while observing the usual $(\overline{M}_{\rm Pl}^2 r)^{-1}$ gravitational potential for distances $r > R$. The experimental bounds on such deviations [23] are displayed in Fig. 1, which shows the constraints on the general form for the gravitational potential

$$V(r) = -G_N\frac{m_1 m_2}{r}\left(1 + \alpha e^{-r/\lambda}\right)\,. \qquad (9)$$

$\delta = 2$ large extra dimensions predict $\alpha = 4$ for compactification on a torus, which leads to the bound $R < 218$ μm. For $\delta > 2$, R is too small for deviations, due to extra dimensional gravity to be detected in mechanical experiments.

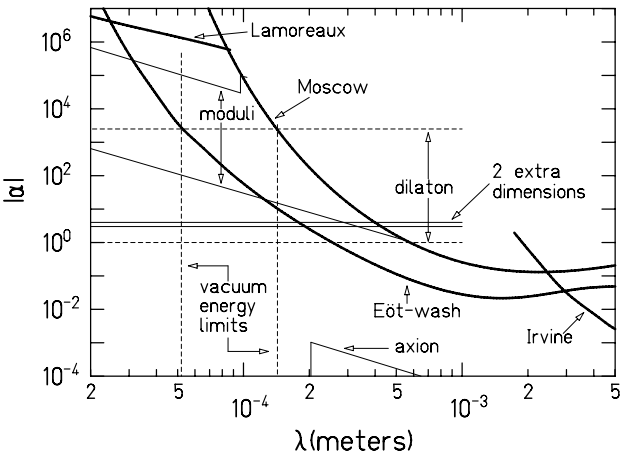

Figure 1: Constraints on deviations from Newton's gravitational force law. The allowed region is below the dark solid lines. From Ref. 23.

Astrophysical and Cosmological Constraints

As first analyzed in Ref. 2, astrophysical and cosmological considerations impose significant constraints on extra-dimensional theories. *Depending on the form of the spectrum of KK excitations of the bulk graviton*, these can imply stringent lower bounds on the gravitational scale $\overline{M}_D$, and corresponding upper bounds on the radii of the extra dimensions, given that

Newton's constant is correctly reproduced by Eq. (3). For extra dimensions of the ADD type, these constraints are significantly more stringent than those from direct collider or micro-gravity experiments for $\delta = 2$.

The spectrum of masses of the graviton KK modes sensitively depend on the topology and geometry of the extra dimensions. The spectral quantity of most direct importance for astrophysical and cosmological constraints is the mass gap between the bulk graviton zero mode and the first excited state. For flat (toroidal) extra dimensions of the type considered by ADD, the gap between the zero-mode and first excited state is given by $1/R$, where R is the (assumed common) radius of the extra dimensions, and the number density of KK modes grows as a power law $\rho(k) \sim V_\delta k^{\delta-1}$. Thus, in this case, the KK modes can be extremely light, *e.g.*, $m_n \geq nR^{-1} \geq n \times 10^{-4}$ eV, for $\delta = 2$, and numerous, $N_{KK} \simeq M_{\rm Pl}^2/\overline{M}_D^2 \leq 10^{32}$. As a result, even though these modes are individually only weakly coupled, with strength $1/M_{\rm Pl}$, they can be copiously produced by energetic processes on our brane.

However, such features are model-dependent. For curved extra dimensions, the spectral density of KK modes can possess a large gap, even approaching $\mathcal{O}(30$ GeV) in extreme cases [24]. Since the typical energy scale in astrophysical and cosmological conditions of interest is at most 100 MeV, the highly curved case avoids the constraints listed below with the exception of A2.

In the warped (RS1) case, these constraints are also avoided, as the scales k and $1/R$ are chosen to be close to the traditional Planck scale, and the resulting spectrum of KK modes has spacing of order a few hundred GeV or greater. In the warped RS2 case, the cosmological constraints are very mild even for $k \gtrsim 1$ mm)$^{-1}$ [22].

We now list the astrophysical and cosmological constraints for *flat extra dimensions* of toroidal type, and *involving solely the bulk graviton* and converted to the conventions of [14]. The constraints can depend upon, (A) only the production of bulk graviton KK modes, such as the case, in the anomalous supernova cooling and overclosure constraints, or (B) both the production and decay back to our brane of the bulk graviton KK modes, such as in the diffuse gamma ray background constraint. The model dependence of the constraints in class (A) is somewhat weaker than for class (B). All bounds become weak for $\delta \geq 4$.

A1 Anomalous cooling of red giants and supernovae due to bulk graviton emission. This was estimated by ADD [2] and calculated in Ref. 25 and further refined in Ref. 26. In particular, the observations of SN1987A place strong constraints on this energy loss mechanism, the dominant astrophysical uncertainty being the unknown core temperature $T_{\rm SN1987A}$ of SN1987A (estimates vary from 30 to 70 MeV). For the case of two flat extra dimensions, a bound of $\overline{M}_D \gtrsim 10$ TeV$(T_{\rm SN1987A}/30$ MeV$)^{1.375}$ is obtained, corresponding to a radius $R \lesssim 7.1 \times 10^{-4}$mm for $T_{\rm SN1987A} = 30$ MeV. For three extra dimensions $R \lesssim 8.5 \times 10^{-7}$mm, equivalent to $\overline{M}_D \gtrsim 0.78$ TeV$(T_{\rm SN1987A}/30$ MeV$)^{1.3}$, while for four or more dimensions the bounds can be extracted from [26], and are less than a TeV.

A2 In large extra dimension scenarios, there are severe limits on the maximum temperature (the 'normalcy temperature' T_*) above which the evolution of the universe must be non-standard [2]. This temperature is found by equating the rates for cooling by the usual process of adiabatic Hubble expansion, and by the new process of evaporation of KK gravitons into the bulk which becomes dominant at high temperatures. For $\overline{M}_D = 1$ TeV, [2] estimate that $T_* \lesssim 10$ MeV for $\delta = 2$, up to $T_* \lesssim 10$ GeV when $\delta = 6$. Since these temperatures are greater than that at big bang nucleosynthesis, there is no unavoidable constraint on $\overline{M}_D$. However, as the normalcy temperature is always below the electroweak phase transition temperature, many aspects of early universe cosmology, including baryogenesis and post-inflation reheating, must be carefully rethought.

B1 Distortion of the diffuse cosmic gamma-ray background due to decay on our brane of bulk gravitons to Standard Model states, and in particular two photons. As discussed above supernova cores will also emit large fluxes of KK gravitons, producing a cosmic background of these particles with energies and masses up to about 100 MeV. Radiative decays then give rise to a diffuse cosmic γ-ray background with $E_\gamma \sim 100$ MeV which is well in excess of the observations if more than 0.5–1% of the SN energy is emitted into the new channel [2]. This argument complements and tightens the cooling limit from the observed duration of the SN 1987A neutrino burst. For two extra dimensions a conservative bound [27] on their radius is $R \lesssim 0.9 \times 10^{-4}$ mm, while for three extra dimensions it is $R \lesssim 1.9 \times 10^{-7}$ mm. This corresponds to $\overline{M}_D \gtrsim 29$ TeV and $\overline{M}_D \gtrsim 1.9$ TeV, respectively.

B2 Anomalous heating of neutron stars by the decays of gravitationally trapped Kaluza-Klein graviton modes. In supernovae core collapse formation of neutron stars, massive KK gravitons would be produced with average velocities $\simeq 0.5c$, leading to many of them being gravitationally retained by the supernova core. Thus, every neutron star would have a halo of KK gravitons which decay into e^+e^-, $\gamma\gamma$, and $\nu\overline{\nu}$, on time scales $\simeq 10^9$ years. The EGRET γ-flux limits for nearby neutron stars then lead to the stringent constraint $\overline{M}_D \gtrsim 90$ TeV, for $\delta = 2$, and $\overline{M}_D \gtrsim 5$ TeV for $\delta = 3$ [28]. Even more stringent, the requirement that neutron stars are not excessively heated by KK decays implies $\overline{M}_D \gtrsim 280$ TeV for $\delta = 2$, and $\overline{M}_D \gtrsim 10$ TeV for $\delta = 3$ [28]. This translates into $R \lesssim 9.6 \times 10^{-7}$ mm and $R \lesssim 1.2 \times 10^{-8}$ mm, respectively.

B3 Over production of long-lived massive bulk gravitons leading to so-called overclosure of the universe [2,29]. This leads to a bound $\overline{M}_D > 2.2/\sqrt{h}$ TeV, or $R < 1.5h \times 10^{-5}m$ for 2 extra flat dimensions, where h is the current Hubble parameter in units of 100km/sMpc. Note that the diffuse gamma-ray background limit is more stringent than the

overclosure limit, so that the massive KK modes of the bulk graviton can not be the dark matter.

In principle, there are ways to evade the bounds that depend on decay back to our brane [7], even in the flat extra dimension case. For example, there may exist extra brane(s) in the bulk on which gravitons can decay, enhancing $\Gamma_{\rm inv}$. However, extreme parameter values are required.

If there are other fields in the bulk, such as right-handed neutrino states [30,31], then there are other potential astrophysical and cosmological constraints in addition to the ones listed above that must be considered [30,32]. This is particularly true of the scalar field that describes changes in the overall size of the extra dimensions (the 'radion') in the ADD case, as this field is, in all cases so far investigated, light with mass as small as 1 mm^{-1}. Moreover, this field has fixed couplings to the energy momentum tensor. Considerations of early universe cosmology typically lead to a severe radion 'moduli problem,' where coherent excitations of this degree of freedom overclose the universe [33]. Finally the extra spatial dimensions must be frozen in size from at least the big-bang nucleosynthesis epoch onwards, so any late motion of the radion is severely constrained, even if it slow enough to satisfy the overclosure constraint.

Constraints from Precision Electroweak Data

A precise description of the contributions to precision electroweak observables from bulk KK states requires a complete understanding of the underlying theory. Indirect contributions arise from the virtual exchange of KK states, and a summation over the entire KK tower must be performed. This summation diverges for $\delta > 1$ due to the non-renormalizability of the full $4+\delta$-dimensional field theory. In a fully consistent theory, such as string theory, the summation would be regularized and finite. Given our present lack of knowledge of the underlying theory, most authors choose to either terminate the summation with an explicit cut-off set to $\overline{M}_D$, or by invoking flexible branes to exponentially damp the sum [11]. These procedures yield naive estimates of the size of indirect KK contributions, and the resulting constraints are hence merely indicative [34].

Constraints in the special case of TeV^{-1} extra dimensions with $\delta = 1$ and rigid branes have been determined in Refs. 35,36. The contributions to the precision observables from tree-level KK gauge interactions, and from the mixing of the KK gauge states with the SM gauge bosons, have been computed, and a global fit to the data yields [35] a restriction on the compactification radius of $R^{-1} \gtrsim 4$ TeV. In addition, the contribution of the KK gauge states in the fit allow for the Higgs boson to be as heavy as ~ 320 GeV, which is larger than that allowed by the SM electroweak fit. These bounds on R^{-1} can be somewhat reduced in the case of flexible branes [12].

In the RS1 model with SM gauge fields in the bulk, the potential contributions to precision electroweak data depend on the placement of the fermions, on the brane or in the bulk. If the fermions are constrained to the TeV-brane, the couplings of the bulk KK gauge states to the SM fermions are large, being given by $\sqrt{2\pi k R}g \simeq 8.4g$. A global fit to the electroweak data, including bulk KK gauge tree-level and mixing contributions, yields [37] the bound $m_1 > 25$ TeV, which sets $\Lambda_\pi \gtrsim 100$ TeV. This constraint can be relaxed if the fermion fields are also placed in the bulk [19,38].

The contributions of bulk gauge KK states to the anomalous magnetic moment of the muon have been found to be small, whereas bulk fermion KK states can yield potentially sizable shifts in $g-2|_\mu$ in the RS scenario [39].

Graviton contributions to precision observables are notoriously problematic due to the non-renormalizability of the theory. Again, naive estimates on the size of such effects can be obtained in an effective field theory employing a cut-off to regulate the theory. In this approach, the cut-off dependent KK graviton contributions to the electroweak data set are found to be small for $\overline{M}_D \gtrsim 1$ TeV in ADD [40], and disfavor small values of $k/\overline{M}_{\rm Pl}$ in RS1 [19].

Collider Signals

Numerous collider searches have been performed which constrain each of the three scenarios. We limit our discussion to the case of low-energy effective Lagrangians, and note that new collider signatures may also be present in the context of string braneworld models, such as the resonant production of higher spin states [41,42].

Large Extra Dimensions: For the case of large flat extra dimensions, the reactions of individual bulk KK graviton states are not detectable, since they interact with the SM fields on the brane with $\overline{M}_{\rm Pl}^{-1}$ strength. However, the mass splittings between the bulk graviton KK states are given by $\Delta m \simeq 5 \times 10^{-4}$ eV, 20 KeV, and 7 MeV for $\delta = 2, 4$ and 6, respectively for $\overline{M}_D = 1$ TeV, and hence, their number density is large at collider energies. This results in observable signatures at the TeV scale. There are two classes of collider processes: (A) the direct production of bulk graviton KK states and (B) graviton KK production and subsequent decay to wall fields on our brane, *i.e.*, bulk graviton KK virtual exchange. Processes of type (A) are more model independent than those of type (B), but both classes are subject to the restrictions of the effective field theory description below $\overline{M}_D$.

The results of experimental searches for processes of both types are tabulated in the Listings.

A Direct Production of KK Gravitons

This class of collider tests is described by the emission of bulk graviton KK states in scattering processes [14,43] such as $e^+e^- \to \gamma/Z+G_n$, $p^{(}\bar{p}^{)} \to g+G_n$, and $Z \to f\bar{f}+G_n$. The graviton appears as missing energy in the detector, behaving as if it were a massive, non-interacting, stable particle. The cross section is computed for a single massive graviton KK state and then summed over the KK tower. This sum can be replaced by an integral weighted by the density of KK states which is cut off by the specific process kinematics. The produced G_n state appears to have a continuous mass

distribution corresponding to the probability of emitting KK gravitons with different extra dimensional momenta.

In e^+e^- collisions, the resulting γ/Z angular and energy distributions can be differentiated from those of the SM background reaction $e^+e^- \to \nu\overline{\nu}\gamma$. In addition, if bulk graviton KK emission is observed, then both parameters $\overline{M}_D$ and δ may be determined by measuring the production rate at different values of $\sqrt{s}$. The cross sections are lowered somewhat in the case of flexible branes [13].

Bulk graviton KK production at hadron colliders results in a mono-jet signal. The effective low-energy theory breaks down for some regions of parameter space, as the parton-level center of mass energy can exceed the value of $\overline{M}_D$. Experiment is then sensitive to the new physics present above this scale. Care must be exercised in interpreting experimental results/simulations, as the effective theory may not be valid over the whole search region.

B Virtual Exchange of KK Gravitons

This class of collider signals consists of bulk graviton KK exchange in all $2 \to 2$ scattering processes [14,44,45]. This results in deviations in cross sections and asymmetries in SM processes, as well as giving rise to new reactions which are not present at tree-level in the SM, such as $gg \to \ell^+\ell^-$. The signature is similar to that expected in the "Quark and Lepton Compositeness" Listings in this *Review*. The exchange process is governed by the effective Lagrangian

$$\mathcal{L} = i\frac{4\lambda}{M_H^4} T_{\mu\nu} T^{\mu\nu} \,. \qquad (10)$$

The amplitude is proportional to the sum over the propagators for the bulk graviton KK tower states which, as above, may be converted to an integral over the density of states. However, in this case, the integral is divergent for $\delta > 1$, and thus introduces a sensitivity to the unknown ultraviolet physics. Several approaches to regulate this integral have been employed: (i) a naive cut-off scheme [14,44], (ii) a flexible brane [11], or (iii) the inclusion of full weakly coupled TeV-scale string theory [42]. The most model independent approach is that of the naive cut-off, with the cut-off being set to $M_H \neq M_D$, to account for the uncertainties from the unknown ultraviolet physics. In addition, the parameter $\lambda = \pm 1$ is usually incorporated. Without a full specification of the UV theory, M_H must be treated as a new independent parameter: it cannot be reliably related to $\overline{M}_D$ and δ. Assuming that the integral is dominated by the lowest dimensional local operator results in a dimension-8 contact-type interaction limit. In the alternate notation of Ref. 14, the coefficient of this effective dimension-8 interaction is $(2/\pi)^{1/4}\Lambda_T = M_H|_{\lambda=+1}$. The resulting angular distributions for fermion pair production are quartic in $\cos\theta$, and thus provide a unique signal for spin-2 exchange.

The simultaneous observation of both classes of processes would signal the existence of large flat extra dimensions, as opposed to other new physics scenarios, as well as determine the parameters of the effective theory.

Once the center of mass energy reaches the scale $\overline{M}_D$, the extra-dimensional gravitational theory described by Eq. (2) becomes strongly coupled, and various exotic production processes might occur. One such possibility is black hole production. Black holes of Schwarzschild radius $R_s \lesssim R$ are substantially altered in the large extra dimension scenario [46], and may have much smaller masses, of order $\overline{M}_D$, than in traditional 4d theories of gravity. Discussions of black hole production at colliders are given in Ref. 47, and constraints on such scenarios from black-holes produced by cosmic rays in the atmosphere are estimated in Ref. 48. Finally, for small-angle elastic scattering, transplanckian collisions, $\sqrt{s} > \overline{M}_D$, can be reliably calculated from the low-energy effective theory and provide additional collider signatures [49].

TeV^{-1}-sized Extra Dimensions: In this scenario, the collider signatures consist of the direct production of the bulk gauge boson KK states at hadron colliders, or the indirect gauge boson KK exchange below production threshold in e^+e^- collisions [50]. This is in direct analogy to the standard signature of new gauge bosons from extended symmetry groups, and is discussed in detail in the extra gauge boson section. The distinction here is that the bulk gauge boson KK coupling strength to the Standard Model fermions is fixed to be $\sqrt{2}g$ for one extra dimension, where g is the SM gauge coupling strength, and the gluon, W, Z, and photon KK states are degenerate, modulo mixing effects. The bounds [35] on the first gauge KK excitation mass are $m_1 > 1.1$ TeV from Drell-Yan production at the Tevatron, and 3.1 TeV from $e^+e^- \to f\bar{f}$ at LEP II. These limits are eclipsed by the constraints from precision electroweak data. If the SM fermions are localized at specific points in the TeV^{-1} dimension, then the exchange of bulk gauge boson KK states in $2 \to 2$ scattering can be used to measure the fermion's wavefunction. The collider signatures of the universal extra dimensions scenario are varied and are discussed in Ref. [17].

Warped Extra Dimensions: In the scenario with warped extra dimensions, the first bulk graviton KK excitation state is of order a TeV, and has TeV^{-1} coupling strength. It can thus be produced as a spin-2 s-channel resonance at colliders. The constraints [18] on the simplest version of the RS model from Run I Tevatron data in the Drell-Yan and dijet resonance channels yield $m_1 \gtrsim 1100\,, 600\,, 200$ GeV for $k/\overline{M}_{\rm Pl} = 1.0\,, 0.1\,, 0.01$, respectively. Measurement of the first graviton KK excitation mass and width would determine the two parameters in this model. Higher energy accelerators may be able to directly observe several states of the bulk graviton KK spectrum; measurement of the mass splittings of the KK states would point to the presence of a warped geometry.

If the KK gravitons are too massive to be produced directly, their indirect exchange in fermion pair production results in a

contact-like interaction. Unlike ADD, the uncertainties associated with the introduction of a cut-off are avoided in this case, since there is only one additional dimension, and the sum over the KK states thus converges. The sensitivities [18] from LEPII data are $\Lambda_\pi = 4.0, 1.5, 0.4$ TeV, and those from Run I Tevatron searches are $\Lambda_\pi = 3.5, 1.0, 0.35$ TeV for $k/\overline{M}_{\rm Pl} = 0.01, 0.1, 1.0$, respectively.

The production rates for graviton KK states are drastically changed in the scenario where fermions are present in the bulk, and these limits are substantially weaker for some values of the fermion bulk mass parameter [19].

The radion, or graviscalar, is predicted to be the lightest new state in this scenario. Its coupling strength to SM fields is v/Λ_π. The signatures for its production and decay are similar to that of the SM Higgs and are examined in Ref. 51. It is allowed to mix with the SM Higgs, which can result in significant shifts in the properties of the Higgs [52].

Limits on R from Deviations in Gravitational Force Law

This section includes limits on the size of extra dimensions from deviations in the Newtonian ($1/r^2$) gravitational force law at short distances. Deviations are parametrized by a gravitational potential of the form $V=-(G\ m\ m'/r^2)[1+\alpha\exp(-r/R)]$. For δ toroidal extra dimensions, $\alpha = 2\delta$.

Limits on R from On-Shell Production of Gravitons: $\delta = 2$

This section includes limits on on-shell production of gravitons in collider and astrophysical processes. Bounds quoted are on R, the assumed common radius of the flat extra dimensions, for $\delta = 2$ extra dimensions. Studies often quote bounds in terms of derived parameter; experiments are actually sensitive to the masses of the KK gravitons: $m_{\vec{n}} = |\vec{n}|/R$. See the Review on "Extra Dimensions" for details. Bounds are given in μm for δ=2.

Limits on R from On-Shell Production of Gravitons: $\delta \geq 3$

This section includes limits similar to those in the previous section, but for $\delta = 3$ extra dimensions. Bounds are given in nm for $\delta = 3$. Entries are also shown for papers examining models with $\delta > 3$.

VALUE (nm)	CL%	DOCUMENT ID		TECN	COMMENT

[5] ABAZOV 03 search for $p\overline{p} \to jG$ at $\sqrt{s}$=1.8 TeV to place bounds on M_D for 2 to 7 extra dimensions, from which these bounds on R are derived. See their paper for bounds on intermediate values of δ. We quote results without the approximate NLO scaling introduced in the paper.
[6] HANNESTAD 03 obtain a limit on R from graviton cooling of supernova SN1987a. Limits for all $\delta \leq 7$ are given in their Tables V and VI.
[7] HANNESTAD 03 obtain a limit on R from gravitons emitted in supernovae and which subsequently decay, contaminating the diffuse cosmic γ background. Limits for all $\delta \leq 7$ are given in their Tables V and VI. These limits supersede those in HANNESTAD 02.
[8] HANNESTAD 03 obtain a limit on R from gravitons emitted in two recent supernovae and which subsequently decay, creating point γ sources. Limits for all $\delta \leq 7$ are given in their Tables V and VI.
[9] HANNESTAD 03 obtain a limit on R from the heating of old neutron starts by the surrounding cloud of trapped KK gravitons. Limits for all $\delta \leq 7$ are given in their Tables V and VI. These limits supersede those in HANNESTAD 02.
[10] HEISTER 03C use the process $e^+e^- \to \gamma G$ at $\sqrt{s} = 189$–209 GeV to place bounds on the size of extra dimensions and the scale of gravity. See their Table 4 for limits with $\delta \leq 6$ for derived limits on M_D.
[11] FAIRBAIRN 01 obtains bounds on R from over production of KK gravitons in the early universe. Bounds are quoted in paper in terms of fundamental scale of gravity. Bounds depend strongly on temperature of QCD phase transition and range from $R<0.13\,\mu$m to 0.001 μm for δ=2; bounds for δ=3,4 can be derived from Table 1 in the paper.
[12] HANHART 01 obtain bounds on R from limits on graviton cooling of supernova SN 1987a using numerical simulations of proto-neutron star neutrino emission.
[13] ABREU 00Z use e^+e^- collisions at $\sqrt{s}$=189 GeV to look for on-shell production of gravitons in association with photons. Bounds are derived for δ=2,4,6.
[14] CASSISI 00 obtain rough bounds on M_D (and thus R) from red giant cooling for δ=2,3. See their paper for details.
[15] ACCIARRI 99R search for the reaction $e^+e^- \to \gamma G$ at $E_{\rm cm}$=189 GeV. Limits on the gravity scale are listed in their Table 4, for $\delta \leq 10$.
[16] ACCIARRI 99S search for $e^+e^- \to ZG$ at $\sqrt{s}$=189 GeV. Limits on the gravity scale are found in their Table 2, for $\delta \leq 4$.
[17] ACOSTA 02H uses the process $p\overline{p} \to \gamma G$ at $\sqrt{s} = 1.8$ TeV to place bounds on R for δ=4,6, and 8: $R<24$ pm, 55 fm, and 2.6 fm respectively. However the kinematics relevant to these bounds are probably outside the validity range of the effective theory.

Mass Limits on M_{TT}

This section includes limits on the cut-off mass scale, M_{TT}, of dimension-8 operators from KK graviton exchange in models of large extra dimensions. Ambiguities in the UV-divergent summation are absorbed into the parameter λ, which is taken to be $\lambda = \pm 1$ in the following analyses. Bounds for $\lambda = -1$ are shown in parenthesis after the bound for $\lambda = +1$, if appropriate. Different papers use slightly different definitions of the mass scale; some popular conventions, M_H and Λ_{TT}, are discussed in the above Review on "Extra Dimensions." All bounds scale as $\lambda^{1/4}$, unless otherwise stated.

[18] ABBIENDI 03D use e^+e^- collisions at $\sqrt{s}$=181–209 to place bounds on the ultraviolate scale M_{TT}, which is equivalent to their definition of M_s.
[19] ACHARD 03D look for deviations in the cross section for $e^+e^- \to ZZ$ from $\sqrt{s}$ = 200–209 GeV to place a bound on M_{TT}.
[20] ADLOFF 03 search for deviations in the differential cross section of $e^\pm p \to e^\pm X$ at $\sqrt{s}$=301 and 319 GeV to place bounds on M_{TT}.
[21] GIUDICE 03 review existing experimental bounds on M_{TT} and derive a combined limit.
[22] GIUDICE 03 place bounds on Λ_6, the coefficient of the gravitationally-induced dimension-6 operator $(2\pi\lambda/\Lambda_6^2)(\sum \overline{f}\gamma_\mu\gamma^5 f)(\sum \overline{f}\gamma^\mu\gamma^5 f)$, using data from a variety of experiments. Results are quoted for $\lambda=\pm 1$ and are independent of δ.
[23] HEISTER 03C use e^+e^- collisions at $\sqrt{s}$= 189–209 GeV to place bounds on the scale of dim-8 gravitational interactions. Their $M_s^\pm$ is equivalent to our M_{TT} with $\lambda=\pm 1$.
[24] ACHARD 02 search for s-channel graviton exchange effects in $e^+e^- \to \gamma\gamma$ at $E_{\rm cm}$ = 192–209 GeV.
[25] ABBOTT 01 search for variations in differential cross sections to e^+e^- and $\gamma\gamma$ final states at the Tevatron.
[26] ABBIENDI 00R uses e^+e^- collisions at $\sqrt{s}$= 189 GeV.

[27] ABREU 00A search for s-channel graviton exchange effects in $e^+e^- \to \gamma\gamma$ at E_{cm}= 189–202 GeV.

[28] ABREU 00S uses e^+e^- collisions at $\sqrt{s}$=183 and 189 GeV.

[29] CHANG 00B derive 3σ limit on M_{TT} of (28,19,15) TeV for δ=(2,4,6) respectively assuming the presence of a torsional coupling in the gravitational action. Highly model dependent.

[30] CHEUNG 00 obtains limits from anomalous diphoton production at OPAL due to graviton exchange. Original limit for δ=4. However, unknown UV theory renders δ dependence unreliable. Original paper works in HLZ convention.

[31] GRAESSER 00 obtains a bound from graviton contributions to $g-2$ of the muon through loops of 0.29 TeV for δ=2 and 0.38 TeV for δ=4,6. Limits scale as $\lambda^{1/2}$. However calculational scheme not well-defined without specification of high-scale theory. See the "Extra Dimensions Review."

[32] HAN 00 calculates corrections to gauge boson self-energies from KK graviton loops and constrain them using S and T. Bounds on M_{TT} range from 0.5 TeV (δ=6) to 1.1 TeV (δ=2); see text. Limits have strong dependence, $\lambda^{\delta+2}$, on unknown λ coefficient.

[33] MATHEWS 00 search for evidence of graviton exchange in CDF and DØ dijet production data. See their Table 2 for slightly stronger δ-dependent bounds. Limits expressed in terms of $M_S^4 = M_{TT}^4/8$.

[34] MELE 00 obtains bound from KK graviton contributions to $e^+e^- \to VV$ (V=γ,W,Z) at LEP. Authors use Hewett conventions.

[35] ABBIENDI 99P search for s-channel graviton exchange effects in $e^+e^- \to \gamma\gamma$ at E_{cm}=189 GeV. The limits $G_+ > 660$ GeV and $G_- > 634$ GeV are obtained from combined E_{cm}=183 and 189 GeV data, where $G_\pm$ is a scale related to the fundamental gravity scale.

[36] ACCIARRI 99M search for the reaction $e^+e^- \to \gamma G$ and s-channel graviton exchange effects in $e^+e^- \to \gamma\gamma$, W^+W^-, ZZ, e^+e^-, $\mu^+\mu^-$, $\tau^+\tau^-$, $q\overline{q}$ at E_{cm}=183 GeV. Limits on the gravity scale are listed in their Tables 1 and 2.

[37] ACCIARRI 99S search for the reaction $e^+e^- \to ZG$ and s-channel graviton exchange effects in $e^+e^- \to \gamma\gamma$, W^+W^-, ZZ, e^+e^-, $\mu^+\mu^-$, $\tau^+\tau^-$, $q\overline{q}$ at E_{cm}=189 GeV. Limits on the gravity scale are listed in their Tables 1 and 2.

[38] BOURILKOV 99 performs global analysis of LEP data on e^+e^- collisions at $\sqrt{s}$=183 and 189 GeV. Bound is on Λ_T.

Direct Limits on Gravitational or String Mass Scale

This section includes limits on the fundamental gravitational scale and/or the string scale from processes which depend directly on one or the other of these scales.

VALUE (TeV)	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •			
$\gtrsim$ 1–2	[39] ANCHORDOQ..02B	RVUE	Cosmic Rays
>0.49	[40] ACCIARRI 00P	L3	$e^+e^- \to e^+e^-$

[39] ANCHORDOQUI 02B derive bound on M_D from non-observation of black hole production in high-energy cosmic rays. Bound is stronger for larger δ, but depends sensitively on threshold for black hole production.

[40] ACCIARRI 00P uses e^+e^- collisions at $\sqrt{s}$= 183 and 189 GeV. Bound on string scale M_S from massive string modes. M_S is defined in hep-ph/0001166 by $M_S(1/\pi)^{1/8}\alpha^{-1/4} = M$ where $(4\pi G)^{-1} = M^{n+2}R^n$.

Limits on $1/R = M_c$

This section includes limits on $1/R = M_C$, the compactification scale in models with TeV extra dimensions, due to exchange of Standard Model KK excitations. See the "Extra Dimension Review" for discussion of model dependence.

VALUE (TeV)	CL%	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
>3.3	95	[41] CORNET 00	RVUE	Electroweak
> 3.3–3.8	95	[42] RIZZO 00	RVUE	Electroweak

[41] CORNET 00 translates a bound on the coefficient of the 4-fermion operator $(\overline{\ell}\gamma_\mu\tau^a\ell)(\overline{\ell}\gamma^\mu\tau^a\ell)$ derived by Hagiwara and Matsumoto into a limit on the mass scale of KK W bosons.

[42] RIZZO 00 obtains limits from global electroweak fits in models with a Higgs in the bulk (3.8 TeV) or on the standard brane (3.3 TeV).

Limits on Mass of Radion

This section includes limits on mass of radion, usually in context of Randall-Sundrum models. See the "Extra Dimension Review" for discussion of model dependence.

VALUE (GeV)	DOCUMENT ID	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •		
$\gtrsim$ 35	[43] MAHANTA 00	$Z \to$ radion $\ell\overline{\ell}$
>120	[44] MAHANTA 00B	$p\overline{p} \to$ radion $\to \gamma\gamma$

[43] MAHANTA 00 obtain bound on radion mass in the RS model. Bound is from Higgs boson search at LEP I.

[44] MAHANTA 00B uses $p\overline{p}$ collisions at $\sqrt{s}$= 1.8 TeV; production via gluon-gluon fusion. Authors assume a radion vacuum expectation value of 1 TeV.

WIMPs and Other Particles Searches for

OMITTED FROM SUMMARY TABLE

WIMPS AND OTHER PARTICLE SEARCHES

Revised March 2002 by K. Hikasa (Tohoku University).

We collect here those searches which do not appear in any of the above search categories. These are listed in the following order:

1. Galactic WIMP (weakly-interacting massive particle) searches
2. Concentration of stable particles in matter
3. Limits on neutral particle production at accelerators
4. Limits on jet-jet resonance in hadron collisions
5. Limits on charged particles in e^+e^- collisions
6. Limits on charged particles in hadron reactions
7. Limits on charged particles in cosmic rays

Note that searches appear in separate sections elsewhere for Higgs bosons (and technipions), other heavy bosons (including W_R, W', Z', leptoquarks, axigluons), axions (including pseudo-Goldstone bosons, Majorons, familons), heavy leptons, heavy neutrinos, free quarks, monopoles, supersymmetric particles, and compositeness. We include specific WIMP searches in the appropriate sections when they yield limits on hypothetical particles such as supersymmetric particles, axions, massive neutrinos, monopoles, *etc.*

We omit papers on CHAMP's, millicharged particles, and other exotic particles. We no longer list for limits on tachyons and centauros. See our 1994 edition for these limits.

GALACTIC WIMP SEARCHES
Cross-Section Limits for Dark Matter Particles (X^0) on Nuclei

These limits are for weakly-interacting stable particles that may constitute the invisible mass in the galaxy. Unless otherwise noted, a local mass density of 0.3 GeV/cm^3 is assumed; see each paper for velocity distribution assumptions. In the papers the limit is given as a function of the X^0 mass. Here we list limits only for typical mass values of 20 GeV, 100 GeV, and 1 TeV. Specific limits on supersymmetric dark matter particles may be found in the Supersymmetry section.

For m_{X^0} = 20 GeV

[1] MIUCHI 03 give model-independent limit σ <35 pb (90%CL) for spin-dependent X^0-proton cross section.
[2] TAKEDA 03 give model-independent limit σ < 0.03 (0.6) nb (90%CL) for spin-dependent χ^0-proton (neutron) cross section.
[3] ANGLOHER 02 limit is for spin-dependent WIMP-Aluminum cross section.
[4] BENOIT 00 find four event categories in Ge detectors and suggest that low-energy surface nuclear recoils can explain anomalous events reported by UKDMC and Saclay NaI experiments.
[5] KLIMENKO 98 limit is for inelastic scattering $X^0\,^{73}$Ge → $X^0\,^{73}$Ge* (13.26 keV).
[6] BELLI 96 limit for inelastic scattering $X^0\,^{129}$Xe → $X^0\,^{129}$Xe*(39.58 keV).
[7] BELLI 96C use background subtraction and obtain σ < 150 pb (< 1.5 fb) (90%CL) for spin-dependent (independent) X^0-proton cross section. The confidence level is from R. Bernabei, private communication, May 20, 1999.
[8] BERNABEI 96 use pulse shape discrimination to enhance the possible signal. The limit here is from R. Bernabei, private communication, September 19, 1997.
[9] SARSA 96 search for annual modulation of WIMP signal. See SARSA 97 for details of the analysis. The limit here is from M.L. Sarsa, private communication, May 26, 1997.
[10] SMITH 96 use pulse shape discrimination to enhance the possible signal. A dark matter density of 0.4 GeV cm^{-3} is assumed.
[11] GARCIA 95 limit is from the event rate. A weaker limit is obtained from searches for diurnal and annual modulation.
[12] SNOWDEN-IFFT 95 look for recoil tracks in an ancient mica crystal. Similar limits are also given for ^{27}Al and ^{28}Si. See COLLAR 96 and SNOWDEN-IFFT 96 for discussion on potential backgrounds.
[13] REUSSER 91 limit here is changed from published (0.04) after reanalysis by authors. J.L. Vuilleumier, private communication, March 29, 1996.

For m_{X^0} = 100 GeV

[14] MIUCHI 03 give model-independent limit for spin-dependent X^0-proton and neutron cross sections. See their Fig. 5.
[15] MIUCHI 03 give model-independent limit σ <35 pb (90%CL) for spin-dependent X^0-proton cross section.
[16] TAKEDA 03 give model-independent limit σ < 0.04 (0.8) nb (90%CL) for spin-dependent χ^0-proton (neutron) cross section.
[17] ANGLOHER 02 limit is for spin-dependent WIMP-Aluminum cross section.
[18] BELLI 02 discuss dependence of the extracted WIMP cross section on the assumptions of the galactic halo structure.
[19] BERNABEI 02C analyze the DAMA data in the scenario in which X^0 scatters into a slightly heavier state as discussed by SMITH 01.
[20] GREEN 02 discusses dependence of extracted WIMP cross section limits on the assumptions of the galactic halo structure.
[21] ULLIO 01 disfavor the possibility that the BERNABEI 99 signal is due to spin-dependent WIMP coupling.
[22] BENOIT 00 find four event categories in Ge detectors and suggest that low-energy surface nuclear recoils can explain anomalous events reported by UKDMC and Saclay NaI experiments.
[23] BERNABEI 00D limit is for inelastic scattering $X^0\,^{129}$Xe → $X^0\,^{129}$Xe (39.58 keV).
[24] AMBROSIO 99 search for upgoing muon events induced by neutrinos originating from WIMP annihilations in the Sun and Earth.
[25] BRHLIK 99 discuss the effect of astrophysical uncertainties on the WIMP interpretation of the BERNABEI 99 signal.
[26] KLIMENKO 98 limit is for inelastic scattering $X^0\,^{73}$Ge → $X^0\,^{73}$Ge* (13.26 keV).
[27] KLIMENKO 98 limit is for inelastic scattering $X^0\,^{73}$Ge → $X^0\,^{73}$Ge* (66.73 keV).
[28] BELLI 96 limit for inelastic scattering $X^0\,^{129}$Xe → $X^0\,^{129}$Xe*(39.58 keV).
[29] BELLI 96C use background subtraction and obtain σ < 0.35 pb (< 0.15 fb) (90%CL) for spin-dependent (independent) X^0-proton cross section. The confidence level is from R. Bernabei, private communication, May 20, 1999.
[30] BERNABEI 96 use pulse shape discrimination to enhance the possible signal. The limit here is from R. Bernabei, private communication, September 19, 1997.
[31] SARSA 96 search for annual modulation of WIMP signal. See SARSA 97 for details of the analysis. The limit here is from M.L. Sarsa, private communication, May 26, 1997.
[32] SMITH 96 use pulse shape discrimination to enhance the possible signal. A dark matter density of 0.4 GeV cm^{-3} is assumed.
[33] GARCIA 95 limit is from the event rate. A weaker limit is obtained from searches for diurnal and annual modulation.
[34] SNOWDEN-IFFT 95 look for recoil tracks in an ancient mica crystal. Similar limits are also given for ^{27}Al and ^{28}Si. See COLLAR 96 and SNOWDEN-IFFT 96 for discussion on potential backgrounds.
[35] BECK 94 uses enriched ^{76}Ge (86% purity).
[36] REUSSER 91 limit here is changed from published (0.3) after reanalysis by authors. J.L. Vuilleumier, private communication, March 29, 1996.

For m_{X^0} = 1 TeV

$< 2.5 \times 10^{-35}$		0	[70] GUSTAFSON	76	CNTR	$\tau > 10^{-7}$ s

[66] ADAMS 97B search for a hadron-like neutral particle produced in pN interactions, which decays into a ρ^0 and a weakly interacting massive particle. Upper limits are given for the ratio to K_L production for the mass range 1.2–5 GeV and lifetime 10^{-9}–10^{-4} s. See also our Light Gluino Section.

[67] GALLAS 95 limit is for a weakly interacting neutral particle produced in 800 GeV/c pN interactions decaying with a lifetime of 10^{-4}–10^{-8} s. See their Figs. 8 and 9. Similar limits are obtained for a stable particle with interaction cross section 10^{-29}–10^{-33} cm^2. See Fig. 10.

[68] AKESSON 91 limit is from weakly interacting neutral long-lived particles produced in pN reaction at 450 GeV/c performed at CERN SPS. Bourquin-Gaillard formula is used as the production model. The above limit is for $\tau > 10^{-7}$ s. For $\tau > 10^{-9}$ s, $\sigma < 10^{-30}$ cm^{-2}/nucleon is obtained.

[69] BADIER 86 looked for long-lived particles at 300 GeV π^- beam dump. The limit applies for nonstrongly interacting neutral or charged particles with mass >2 GeV. The limit applies for particle modes, $\mu^+\pi^-$, $\mu^+\mu^-$, $\pi^+\pi^-$X, $\pi^+\pi^-\pi^\pm$ etc. See their figure 5 for the contours of limits in the mass-τ plane for each mode.

[70] GUSTAFSON 76 is a 300 GeV FNAL experiment looking for heavy ($m > 2$ GeV) long-lived neutral hadrons in the M4 neutral beam. The above typical value is for $m = 3$ GeV and assumes an interaction cross section of 1 mb. Values as a function of mass and interaction cross section are given in figure 2.

Production of New Penetrating Non-ν Like States in Beam Dump

VALUE	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
	[71] LOSECCO	81	CALO	28 GeV protons

[71] No excess neutral-current events leads to σ(production) $\times$ σ(interaction)$\times$acceptance $< 2.26 \times 10^{-71}$ cm^4/nucleon^2 (CL = 90%) for light neutrals. Acceptance depends on models (0.1 to 4. $\times 10^{-4}$).

LIMITS ON JET-JET RESONANCES

Heavy Particle Production Cross Section in $p\overline{p}$

Limits are for a particle decaying to two hadronic jets.

Units(pb)	CL%	Mass(GeV)	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •					
			[72] ABE	99F CDF	1.8 TeV $p\overline{p} \rightarrow b\overline{b}$+ anything
			[73] ABE	97G CDF	1.8 TeV $p\overline{p} \rightarrow$ 2 jets

[75] ACKERSTAFF 98P search for pair production of long-lived charged particles at E_{cm} between 130 and 183 GeV and give limits $\sigma <$(0.05–0.2) pb (95%CL) for spin-0 and spin-1/2 particles with m=45–89.5 GeV, charge 1 and 2/3. The limit is translated to the cross section at E_{cm}=183 GeV with the s dependence described in the paper. See their Figs. 2–4.

[76] ABREU 97D search for pair production of long-lived particles and give limits $\sigma <$(0.4–2.3) pb (95%CL) for various center-of-mass energies E_{cm}=130–136, 161, and 172 GeV, assuming an almost flat production distribution in cosθ.

[77] BARATE 97K search for pair production of long-lived charged particles at E_{cm} = 130, 136, 161, and 172 GeV and give limits $\sigma <$(0.2–0.4) pb (95%CL) for spin-0 and spin-1/2 particles with m=45–85 GeV. The limit is translated to the cross section at E_{cm}=172 GeV with the E_{cm} dependence described in the paper. See their Figs. 2 and 3 for limits on J = 1/2 and J = 0 cases.

[78] AKERS 95R is a CERN-LEP experiment with $W_{cm} \sim m_Z$. The limit is for the production of a stable particle in multihadron events normalized to $\sigma(e^+e^- \rightarrow$ hadrons). Constant phase space distribution is assumed. See their Fig. 3 for bounds for $Q = \pm 2/3$, $\pm 4/3$.

[79] BUSKULIC 93C is a CERN-LEP experiment with $W_{cm} = m_Z$. The limit is for a pair or single production of heavy particles with unusual ionization loss in TPC. See their Fig. 5 and Table 1.

[80] ADACHI 90C is a KEK-TRISTAN experiment with W_{cm} = 52–60 GeV. The limit is for pair production of a scalar or spin-1/2 particle. See Figs. 3 and 4.

[81] ADACHI 90E is KEK-TRISTAN experiment with W_{cm} = 52–61.4 GeV. The above limit is for inclusive production cross section normalized to $\sigma(e^+e^- \rightarrow \mu^+\mu^-)\cdot\beta(3-\beta^2)/2$, where $\beta = (1 - 4m^2/W_{cm}^2)^{1/2}$. See the paper for the assumption about the production mechanism.

[82] KINOSHITA 82 is SLAC PEP experiment at W_{cm} = 29 GeV using lexan and ^{39}Cr plastic sheets sensitive to highly ionizing particles.

[83] BARTEL 80 is DESY-PETRA experiment with W_{cm} = 27–35 GeV. Above limit is for inclusive pair production and ranges between $1. \times 10^{-1}$ and $1. \times 10^{-2}$ depending on mass and production momentum distributions. (See their figures 9, 10, 11).

Branching Fraction of Z^0 to a Pair of Stable Charged Heavy Fermions

• • • We do not use the following data for averages, fits, limits, etc. • • •					
$<5 \times 10^{-6}$	95	[84] AKERS	95R OPAL		m= 40.4–45.6 GeV
$<1 \times 10^{-3}$	95	AKRAWY	90O OPAL		m = 29–40 GeV

[84] AKERS 95R give the 95% CL limit $\sigma(X\overline{X})/\sigma(\mu\mu) < 1.8\times10^{-4}$ for the pair production of singly- or doubly-charged stable particles. The limit applies for the mass range 40.4–45.6 GeV for $X^{\pm}$ and < 45.6 GeV for $X^{\pm\pm}$. See the paper for bounds for $Q = \pm 2/3$, $\pm 4/3$.

LIMITS ON CHARGED PARTICLES IN HADRONIC REACTIONS

Heavy Particle Production Cross Section

<0.05	95		[85] ABE	92J CDF		m=50–200 GeV
<30–130			[86] CARROLL	78 SPEC		m=2–2.5 GeV
<100		0	[87] LEIPUNER	73 CNTR		m=3–11 GeV

[85] ABE 92J look for pair production of unit-charged particles which leave detector before decaying. Limit shown here is for m=50 GeV. See their Fig. 5 for different charges and stronger limits for higher mass.

[86] CARROLL 78 look for neutral, $S = -2$ dihyperon resonance in $pp \rightarrow 2K^+X$. Cross section varies within above limits over mass range and p_{lab} = 5.1–5.9 GeV/c.

[87] LEIPUNER 73 is an NAL 300 GeV p experiment. Would have detected particles with lifetime greater than 200 ns.

$<3.0 \times 10^{-36}$		0	[95] DORFAN	65	CNTR		Fe target m=3–7 GeV

[88] BALDIN 76 is a 70 GeV Serpukhov experiment. Value is per Al nucleus at $\theta = 0$. For other charges in range -0.5 to -3.0, CL = 90% limit is $(2.6 \times 10^{-36})/|(\text{charge})|$ for mass range (2.1–9.4 GeV) $\times |(\text{charge})|$. Assumes stable particle interacting with matter as do antiprotons.

[89] ALBROW 75 is a CERN ISR experiment with E_{cm} = 53 GeV. θ = 40 mr. See figure 5 for mass ranges up to 35 GeV.

[90] JOVANOVICH 75 is a CERN ISR 26+26 and 15+15 GeV pp experiment. Figure 4 covers ranges Q = 1/3 to 2 and m = 3 to 26 GeV. Value is per GeV momentum.

[91] APPEL 74 is NAL 300 GeV pW experiment. Studies forward production of heavy (up to 24 GeV) charged particles with momenta 24–200 GeV (−charge) and 40–150 GeV (+charge). Above typical value is for 75 GeV and is per GeV momentum per nucleon.

[92] ALPER 73 is CERN ISR 26+26 GeV pp experiment. $p >$0.9 GeV, 0.2 < β <0.65.

[93] ANTIPOV 71B is from same 70 GeV p experiment as ANTIPOV 71C and BINON 69.

[94] ANTIPOV 71C limit inferred from flux ratio. 70 GeV p experiment.

[95] DORFAN 65 is a 30 GeV/c p experiment at BNL. Units are per GeV momentum per nucleus.

Long-Lived Heavy Particle Invariant Cross Section

VALUE (cm^2/GeV^2/N)	CL%	EVTS	DOCUMENT ID		TECN	CHG	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •							
$< 5 \times 10^{-35}$–7×10^{-33}	90	0	[96] BERNSTEIN	88	CNTR		
$< 5 \times 10^{-37}$–7×10^{-35}	90	0	[96] BERNSTEIN	88	CNTR		
$<2.5 \times 10^{-36}$	90	0	[97] THRON	85	CNTR	–	Q= 1, m=4–12 GeV
$<1. \times 10^{-35}$	90	1	[97] THRON	85	CNTR	+	Q= 1, m=4–12 GeV
$<6. \times 10^{-33}$	90	0	[98] ARMITAGE	79	SPEC		m=1.87 GeV
$<1.5 \times 10^{-33}$	90	0	[98] ARMITAGE	79	SPEC		m=1.5–3.0 GeV

$<1.1 \times 10^{-37}$	90	0	[100] CUTTS	78	CNTR		m=4–10 GeV
$<3.0 \times 10^{-37}$	90	0	[101] VIDAL	78	CNTR		m=4.5–6 GeV

[96] BERNSTEIN 88 limits apply at x = 0.2 and p_T = 0. Mass and lifetime dependence of limits are shown in the regions: m = 1.5–7.5 GeV and $\tau = 10^{-8}$–2×10^{-6} s. First number is for hadrons; second is for weakly interacting particles.

[97] THRON 85 is FNAL 400 GeV proton experiment. Mass determined from measured velocity and momentum. Limits are for $\tau > 3 \times 10^{-9}$ s.

[98] ARMITAGE 79 is CERN-ISR experiment at E_{cm} = 53 GeV. Value is for x = 0.1 and p_T = 0.15. Observed particles at m = 1.87 GeV are found all consistent with being antideuterons.

[99] BOZZOLI 79 is CERN-SPS 200 GeV pN experiment. Looks for particle with τ larger than 10^{-8} s. See their figure 11–18 for production cross-section upper limits vs mass.

[100] CUTTS 78 is pBe experiment at FNAL sensitive to particles of $\tau > 5 \times 10^{-8}$ s. Value is for -0.3 <x<0 and p_T = 0.175.

[101] VIDAL 78 is FNAL 400 GeV proton experiment. Value is for x = 0 and p_T = 0. Puts lifetime limit of $< 5 \times 10^{-8}$ s on particle in this mass range.

Long-Lived Heavy Particle Production (σ(Heavy Particle) / $\sigma(\pi)$)

$< 1.0 \times 10^{-9}$		0	BRIATORE	76	ELEC		
$< 7. \times 10^{-10}$	90	0	YOCK	75	ELEC	±	$Q > 7e$ or $< -7e$
$> 6. \times 10^{-9}$		5	[117] YOCK	74	CNTR		m >6 GeV
$< 3.0 \times 10^{-8}$		0	DARDO	72	CNTR		
$< 1.5 \times 10^{-9}$		0	TONWAR	72	CNTR		m >10 GeV
$< 3.0 \times 10^{-10}$		0	BJORNBOE	68	CNTR		m >5 GeV
$< 5.0 \times 10^{-11}$	90	0	JONES	67	ELEC		m=5–15 GeV

[109] SAITO 90 candidates carry about 450 MeV/nucleon. Cannot be accounted for by conventional backgrounds. Consistent with strange quark matter hypothesis.
[110] MINCER 85 is high statistics study of calorimeter signals delayed by 20–200 ns. Calibration with AGS beam shows they can be accounted for by rare fluctuations in signals from low-energy hadrons in the shower. Claim that previous delayed signals including BJORNBOE 68, DARDO 72, BHAT 82, SAKUYAMA 83B below may be due to this fake effect.
[111] SAKUYAMA 83B analyzed 6000 extended air shower events. Increase of delayed particles and change of lateral distribution above 10^{17} eV may indicate production of very heavy parent at top of atmosphere.
[112] BHAT 82 observed 12 events with delay $> 2. \times 10^{-8}$ s and with more than 40 particles. 1 eV has good hadron shower. However all events are delayed in only one of two detectors in cloud chamber, and could not be due to strongly interacting massive particle.
[113] MARINI 82 applied PEP-counter for TOF. Above limit is for velocity = 0.54 of light. Limit is inconsistent with YOCK 80 YOCK 81 events if isotropic dependence on zenith angle is assumed.
[114] YOCK 81 saw another 3 events with $Q = \pm 1$ and m about $4.5 m_p$ as well as 2 events with m >5.3m_p, $Q = \pm 0.75 \pm 0.05$ and m >2.8m_p, $Q = \pm 0.70 \pm 0.05$ and 1 event with $m = (9.3 \pm 3.)m_p$, $Q = \pm 0.89 \pm 0.06$ as possible heavy candidates.
[115] YOCK 80 events are with charge exactly or approximately equal to unity.
[116] BHAT 78 is at Kolar gold fields. Limit is for $\tau > 10^{-6}$ s.
[117] YOCK 74 events could be tritons.

Superheavy Particle (Quark Matter) Flux in Cosmic Rays

[118] AMBROSIO 00B searched for quark matter ("nuclearites") in the velocity range $(10^{-5}–1)\,c$. The listed limit is for $2 \times 10^{-3}\,c$.
[119] ASTONE 93 searched for quark matter ("nuclearites") in the velocity range $(10^{-3}–1)\,c$. Their Table 1 gives a compilation of searches for nuclearites.
[120] AHLEN 92 searched for quark matter ("nuclearites"). The bound applies to velocity $< 2.5 \times 10^{-3}\,c$. See their Fig. 3 for other velocity/c and heavier mass range.
[121] NAKAMURA 91 searched for quark matter in the velocity range $(4 \times 10^{-5}–1)\,c$.
[122] ORITO 91 searched for quark matter. The limit is for the velocity range $(10^{-4}–10^{-3})\,c$.
[123] LIU 88 searched for quark matter ("nuclearites") in the velocity range $(2.5 \times 10^{-3}–1)c$. A less stringent limit of 5.8×10^{-11} applies for $(1–2.5) \times 10^{-3}c$.
[124] BARISH 87 searched for quark matter ("nuclearites") in the velocity range $(2.7 \times 10^{-4}–5 \times 10^{-3})c$.
[125] NAKAMURA 85 at KEK searched for quark-matter. These might be lumps of strange quark matter with roughly equal numbers of u, d, s quarks. These lumps or nuclearites were assumed to have velocity of $(10^{-4}–10^{-3})\,c$.
[126] ULLMAN 81 is sensitive for heavy slow singly charge particle reaching earth with vertical velocity 100–350 km/s.

COLOR FIGURES

Electroweak model and constraints on new physics (p.122)

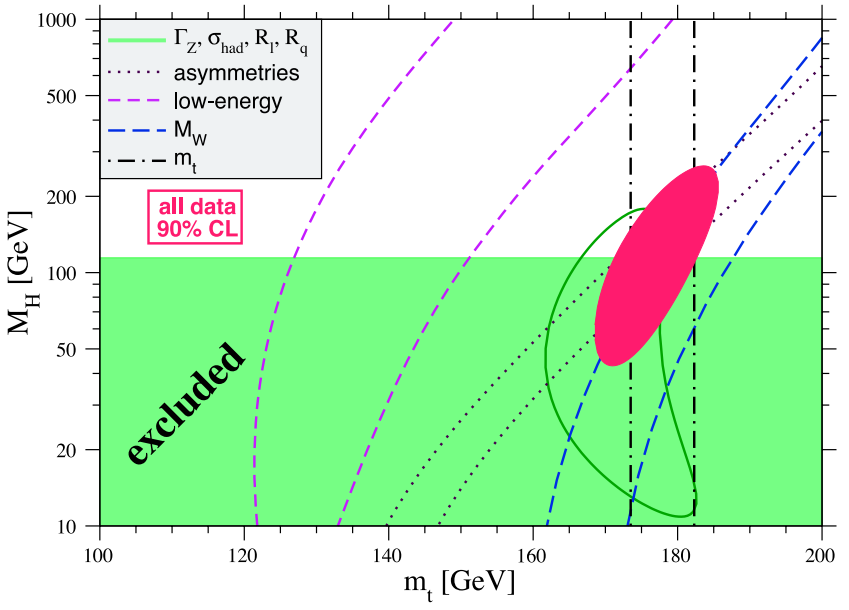

Figure 10.1: One-standard-deviation (39.35%) uncertainties in M_H as a function of m_t for various inputs, and the 90% CL region ($\Delta\chi^2 = 4.605$) allowed by all data. $\alpha_s(M_Z) = 0.120$ is assumed except for the fits including the Z-lineshape data. The 95% direct lower limit from LEP 2 is also shown.

Electroweak model and constraints on new physics (p.123)

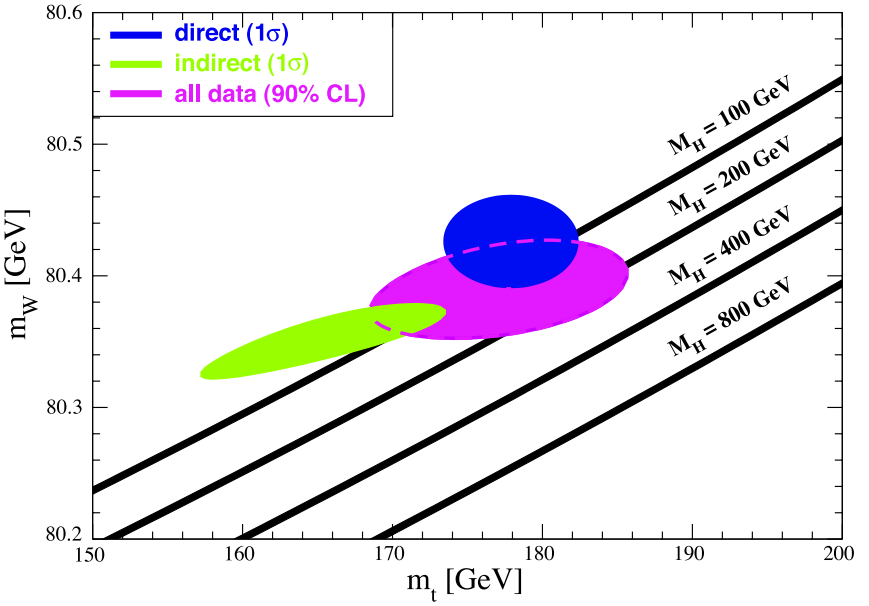

Figure 10.2: One-standard-deviation (39.35%) region in M_W as a function of m_t for the direct and indirect data, and the 90% CL region ($\Delta\chi^2 = 4.605$) allowed by all data. The SM prediction as a function of M_H is also indicated. The widths of the M_H bands reflect the theoretical uncertainty from $\alpha(M_Z)$.

Electroweak model and constraints on new physics (p.125)

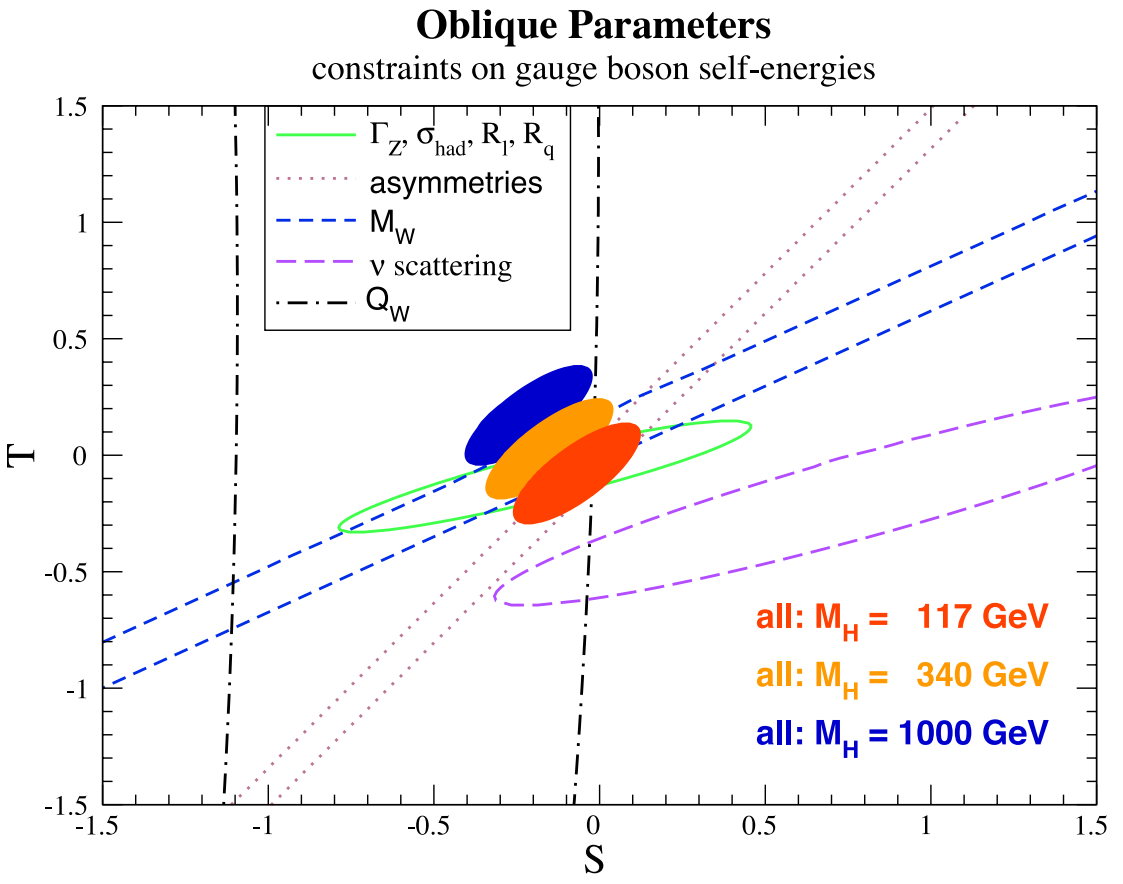

Figure 10.3: 1 σ constraints (39.35%) on S and T from various inputs. S and T represent the contributions of new physics only. (Uncertainties from m_t are included in the errors.) The contours assume $M_H = 117$ GeV except for the central and upper 90% CL contours allowed by all data, which are for $M_H = 340$ GeV and 1000 GeV, respectively. Data sets not involving M_W are insensitive to U. Due to higher order effects, however, $U = 0$ has to be assumed in all fits. α_s is constrained using the τ lifetime as additional input in all fits.

CKM quark-mixing matrix (p.133)

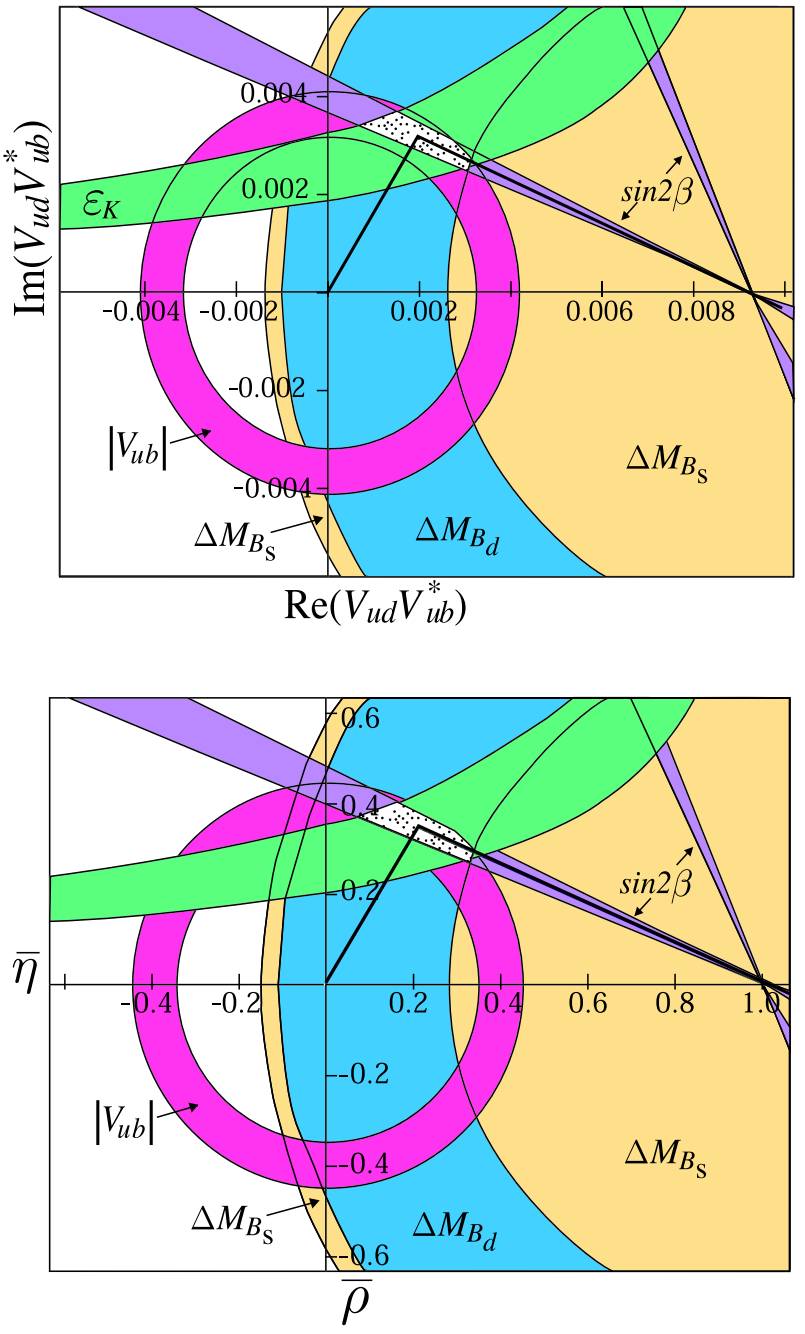

Figure 11.2: Constraints from the text on the position of the apex, A, of the unitarity triangle following from $|V_{ub}|$,B mixing, ϵ, and $\sin 2\beta$. A possible unitarity triangle is shown with A in the preferred region.

Neutrino mixing (p.148)

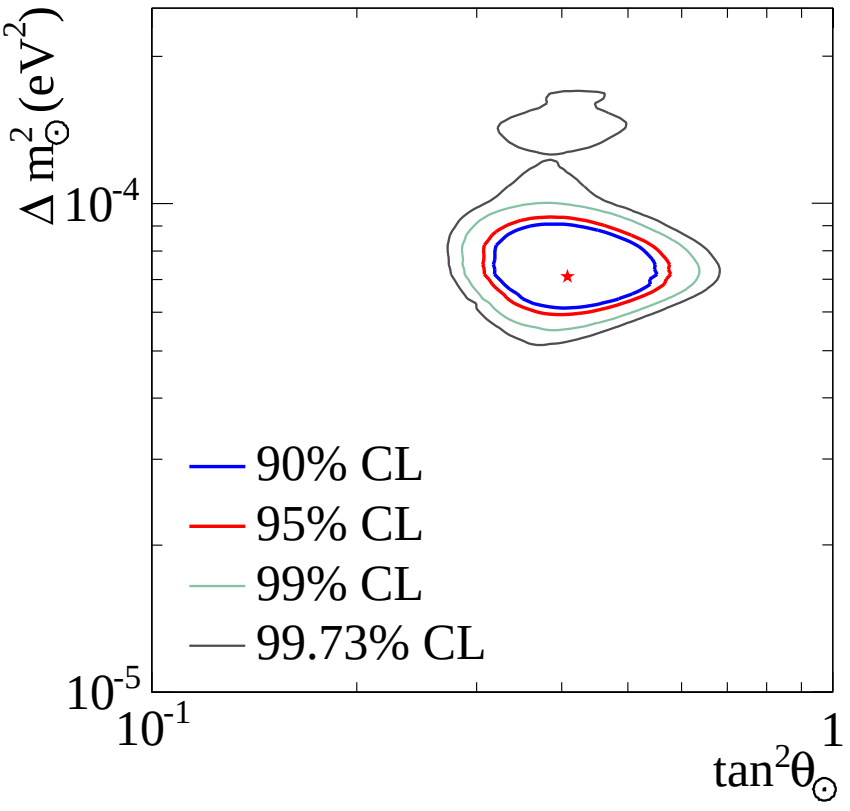

Figure 13.1: The region allowed for the neutrino parameters $\Delta m^2_\odot$ and $\theta_\odot$ by the solar and KamLAND data. The best-fit point, indicated by the star, is $\Delta m^2_\odot = 7.1 \times 10^{-5}\,\mathrm{eV}^2$ and $\theta_\odot = 32.5°$.

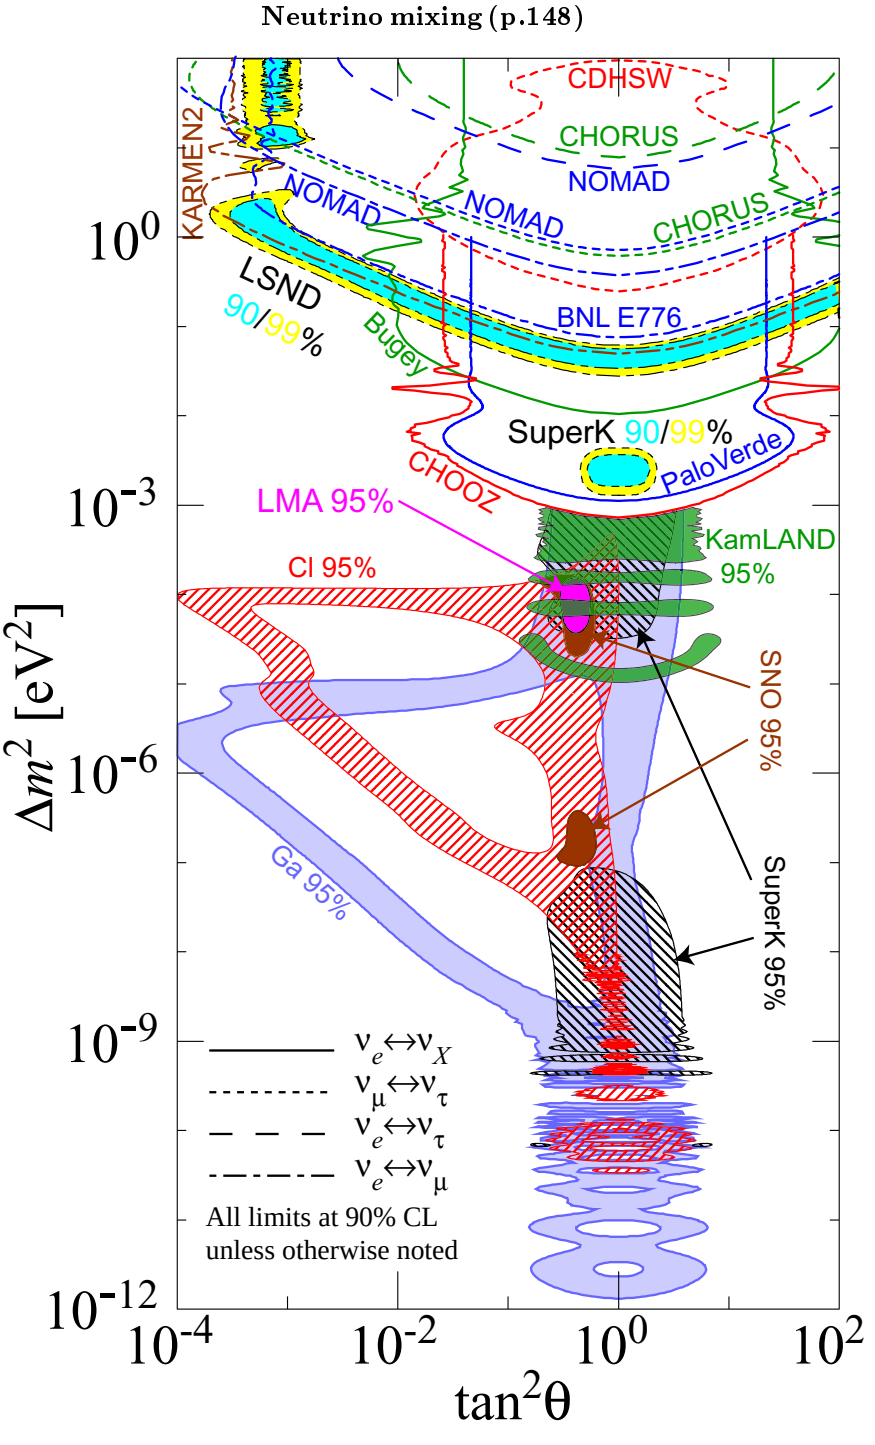

Figure 13.2: The regions of squared-mass splitting and mixing angle favored or excluded by various experiments. This figure was contributed by H. Murayama (University of California, Berkeley). References to the data used in the figure can be found at `http://hitoshi.berkeley.edu/neutrino/ref.html`.

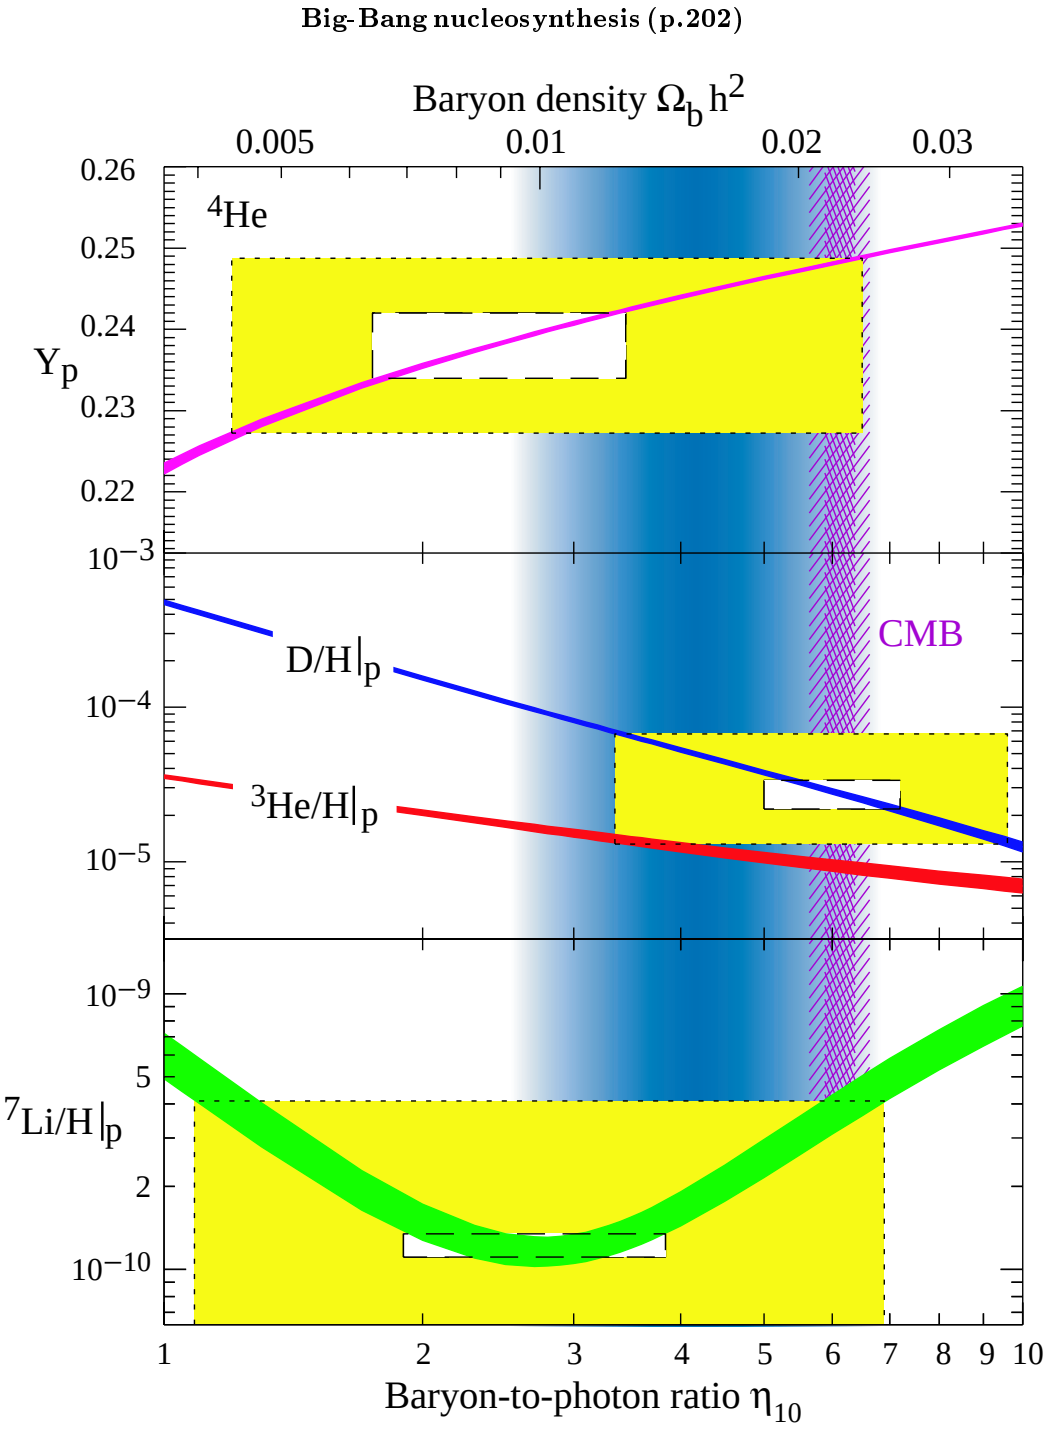

Figure 20.1: The abundances of ^{4}He, D, ^{3}He and ^{7}Li as predicted by the standard model of big-bang nucleosynthesis. Boxes indicate the observed light element abundances (smaller boxes: 2σ statistical errors; larger boxes: $\pm 2\sigma$ statistical and systematic errors added in quadrature). The narrow vertical band indicates the CMB measure of the cosmic baryon density.

The Cosmological Parameters (p.210)

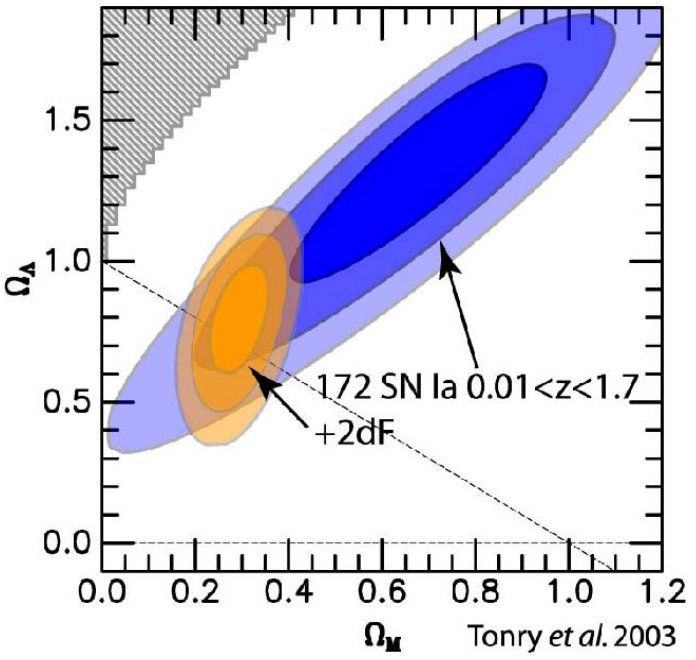

Figure 21.1: This shows the preferred region in the Ω_m–Ω_Λ plane from a study of 172 supernovae, and also how the constraints tighten when the 2dF galaxy redshift survey power spectrum is added as an additional constraint. [Reproduced with permission from Tonry *et al.* [16].]

The Cosmological Parameters (p.213)

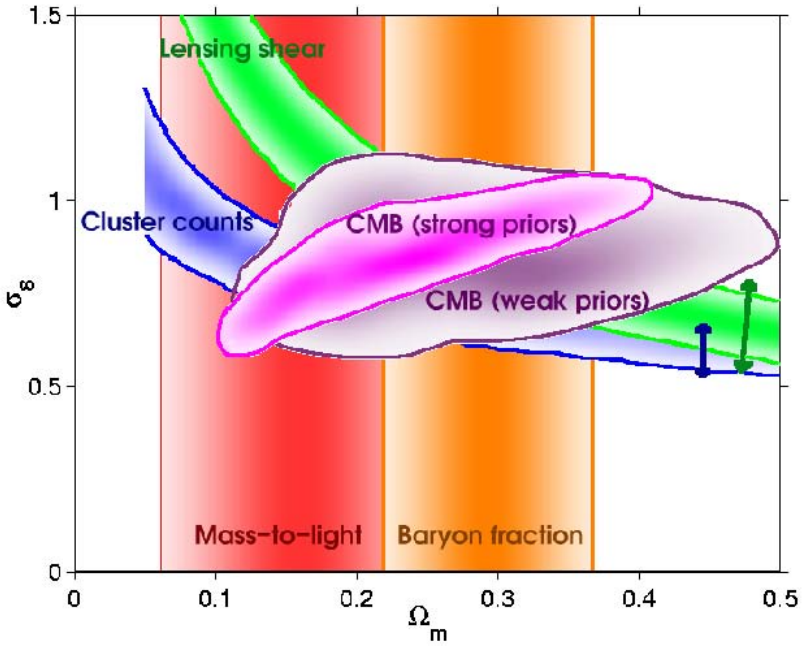

Figure 21.4: Various constraints shown in the Ω_m–σ_8 plane. [Figure provided by Sarah Bridle; see also Ref. 42.]

The Mass of the W boson (p.336)

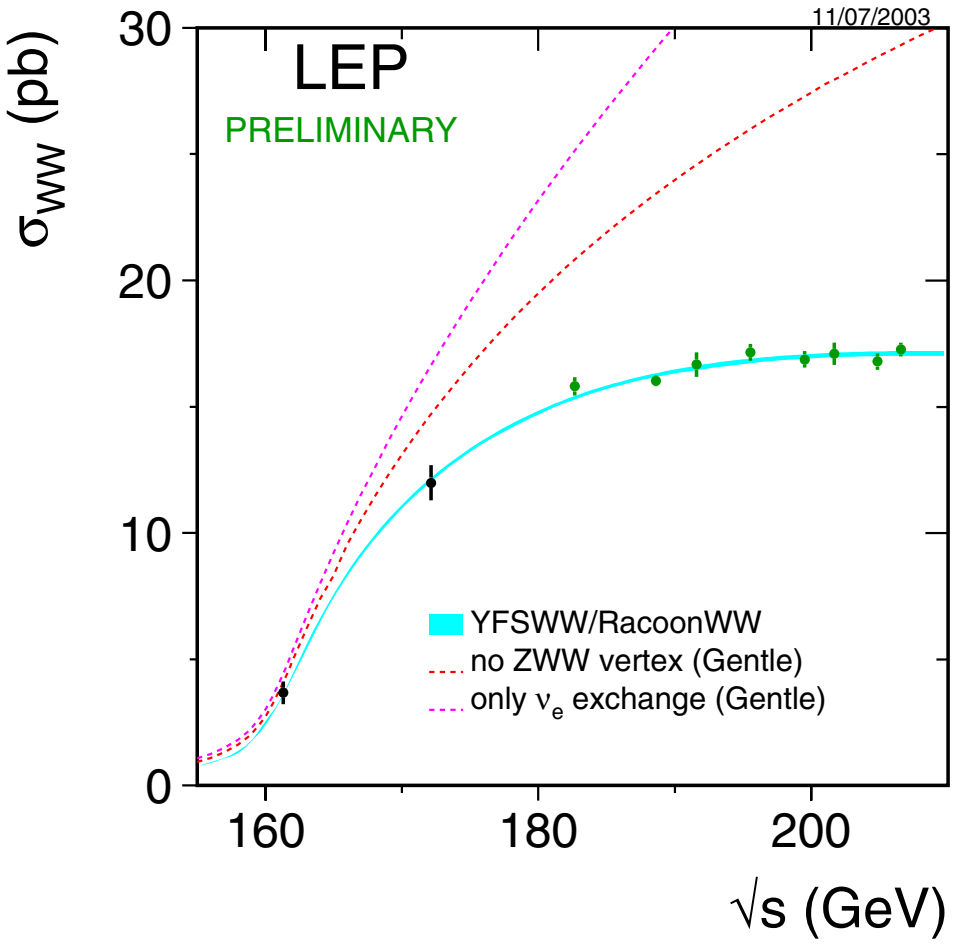

Figure 1: The W–pair cross section as a function of the center–of–mass energy. The data points are the LEP averages. The solid lines are predictions from different models of WW production. For comparison the figure contains also the cross section if the ZWW coupling did not exist (dashed line), or if only the t–channel ν_e exchange diagram existed (dotted-dashed line). (Figure from `http://lepewwg.web.cern.ch/LEPEWWG/lepww/4f/Summer03/wwxsec/nocouplings/2003.eps`)

Searches for Higgs Bosons (p.366)

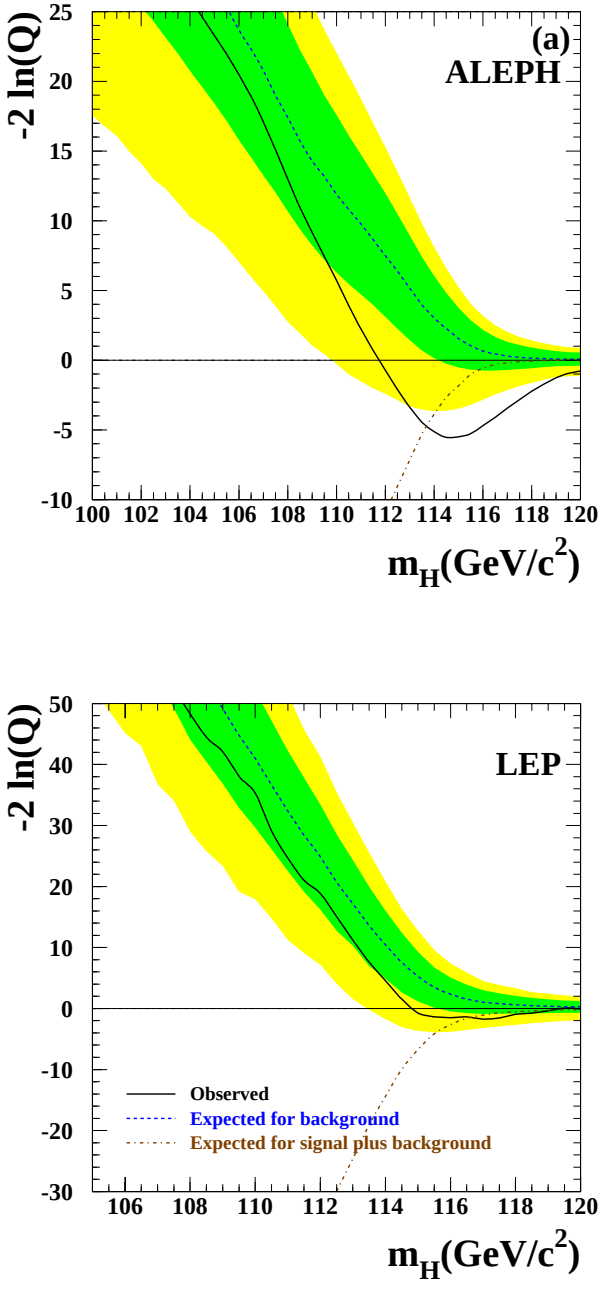

Figure 2: Observed (solid line), and expected behaviors of the test statistic $-2\ln Q$ for the background (dashed line), and the signal + background hypothesis (dash-dotted line) as a function of the test mass m_H. Top: ALEPH data alone; bottom: LEP data combined [27]. The dark and light shaded areas represent the 68% and 95% probability bands about the background expectation.

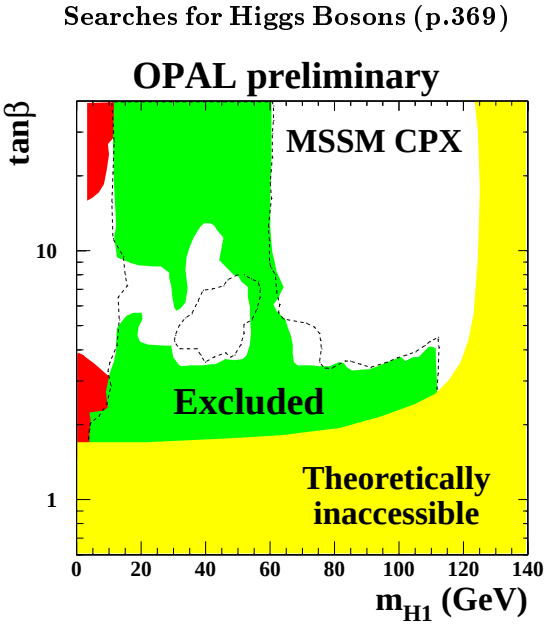

Figure 4: The 95% CL bounds on m_{H_1} and $\tan\beta$ in the CPX MSSM scenario with $\mu = 2$ TeV and $M_{\rm SUSY} = 500$ GeV, from a preliminary OPAL analysis [36]. The shaded areas are excluded either by the model or by the experiment. The areas delimited by the dashed lines are expected to be excluded on the basis of Monte Carlo simulations. The top mass is fixed to 174.3 GeV.

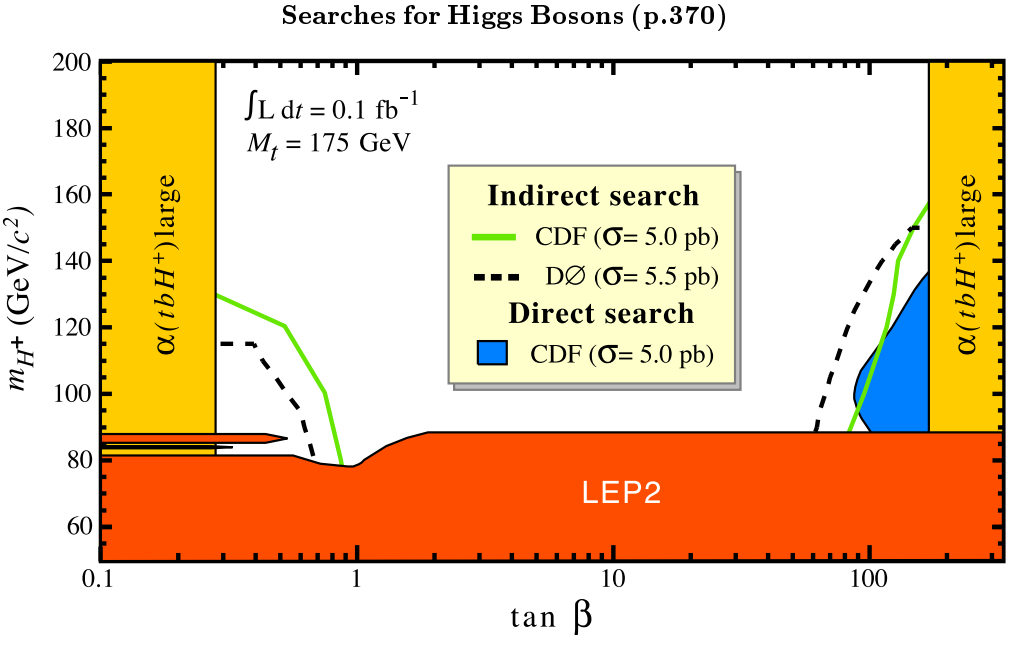

Figure 5: Summary of the 95% CL exclusions in the (m_{H^+}, $\tan\beta$) plane from DØ [45] and CDF [47], using various indirect and direct observation techniques (the regions below the curves are excluded). The two experiments use slightly different theoretical $t\bar{t}$ cross sections, as indicated. The shaded domains at extreme values of $\tan\beta$ are not considered in these searches, since there the tbH^+ coupling becomes large and perturbative calculations do not apply. The dark region labeled LEP2 is excluded by LEP [42].

Understanding two-flavor oscillation parameters and limits (p.451)

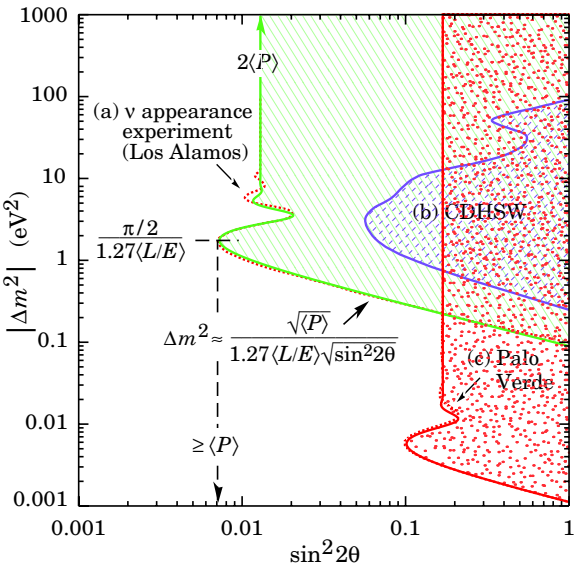

Figure 1: Neutrino oscillation parameter ranges excluded by three experiments. The dotted line in (a) is from an older Los Alamos appearance experiment (DURKIN 88), while the solid line is obtained from Eq. (2) using the parameters $\langle P\rangle = 0.0065$, $\Delta m^2 = 0.095$ eV^2 at $\sin^2 2\theta = 1$, and $\sigma_b/b_0 = 0.23$; (b) is a disappearance experiment with the flux obtained from the data in a long detector (DYDAK 84); and for (c) the Palo Verde reactor experiment result (BOEHM 01) is shown by the dotted line. In this experiment the flux at production is known. The solid line is calculated from Eq. (2) using $\langle P\rangle = 0.084$, $\Delta m^2 = 0.0011$ eV^2 at $\sin^2 2\theta = 1$, and $\sigma_b/b_0 = 0.3$. The experiments have been chosen for illustrative purposes, and none represents a current best limit.

Solar neutrinos (p.460)

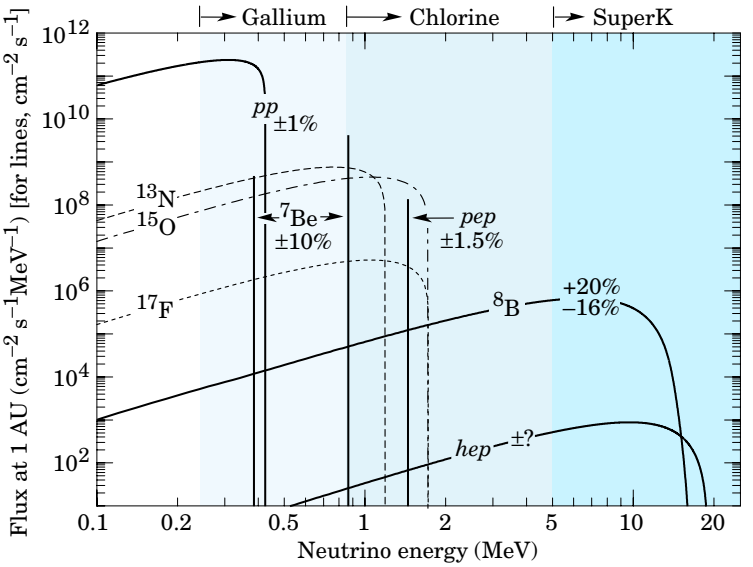

Figure 1: The solar neutrino spectrum predicted by the standard solar model. The neutrino fluxes from continuum sources are given in units of number cm^{-2}s^{-1}MeV^{-1} at one astronomical unit, and the line fluxes are given in number cm^{-2}s^{-1}. Spectra for the *pp* chain, shown by the solid curves, are courtesy of J.N. Bahcall (2001). Spectra for the CNO chain are shown by the dotted curves, and are also courtesy of J.N. Bahcall (1995).

Solar neutrinos (p.462)

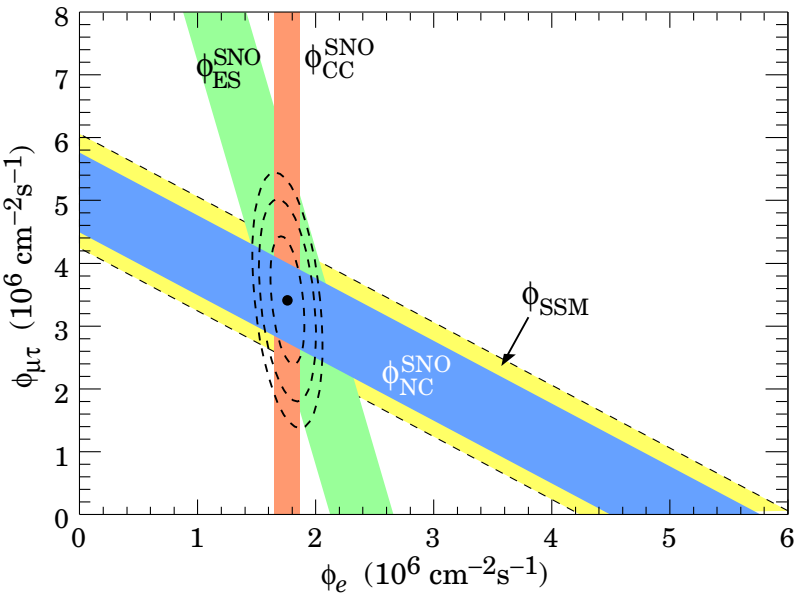

Figure 2: Fluxes of ^{8}B solar neutrinos, $\phi(\nu_e)$, and $\phi(\nu_{\mu \text{ or } \tau})$, deduced from the SNO's charged-current (CC), ν_e elastic scattering (ES), and neutral-current (NC) results for pure D_2O. The standard solar model prediction [9] is also shown. The bands represent the 1σ error. The contours show the 68%, 95%, and 99% joint probability for $\phi(\nu_e)$ and $\phi(\nu_{\mu \text{ or } \tau})$. This figure is courtesy of K.T. Lesko (LBNL).

Solar neutrinos (p.464)

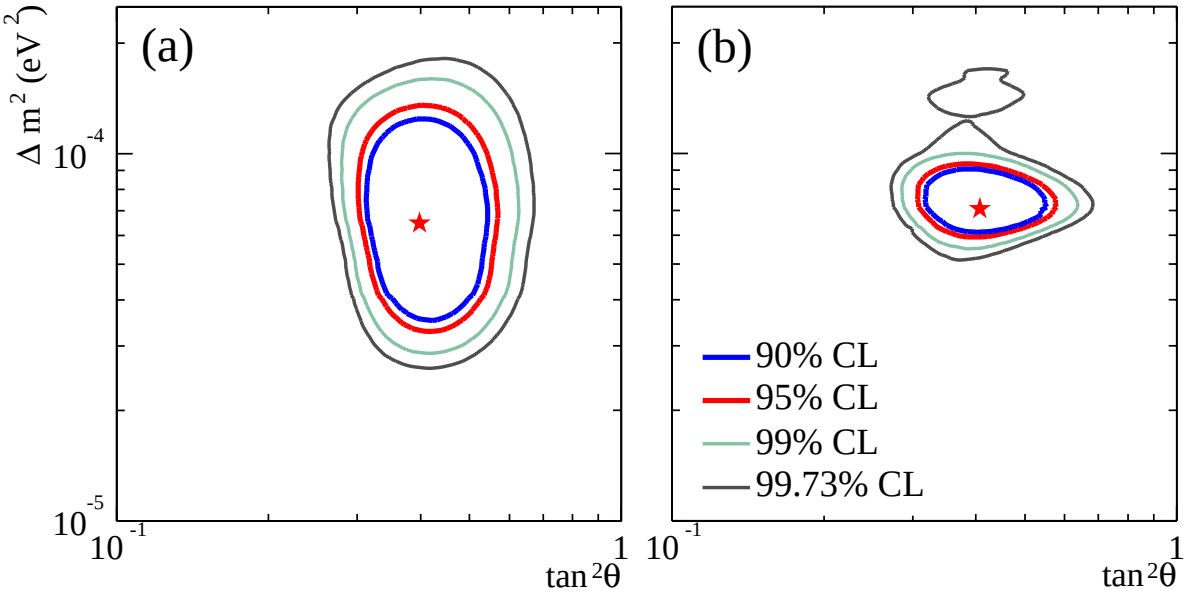

Figure 4: Global neutrino oscillation contours given by the SNO Collaboration assuming that the ^{8}B neutrino flux is free and the *hep* neutrino flux is fixed. (a) Solar global analysis. (b) Solar global + KamLAND. For details, see Ref. [8].

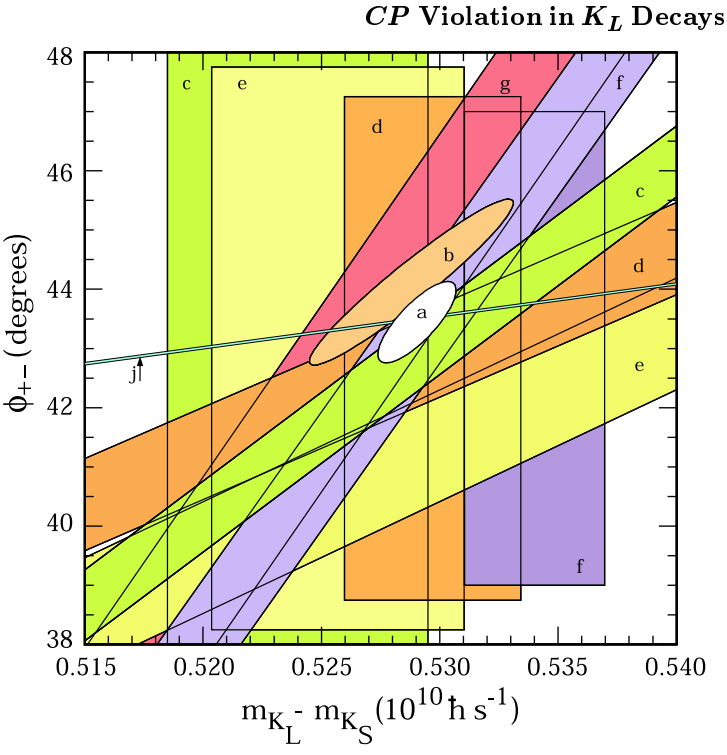

Figure 1: ϕ_{+-} vs Δm for experiments which do not assume CPT invariance. Δm measurements appear as vertical bands spanning $\Delta m \pm 1\sigma$, cut near the top and bottom to aid the eye. Most ϕ_{+-} measurements appear as diagonal bands spanning $\phi_{+-} \pm \sigma_\phi$. Data are labeled by letters: "b"–FNAL KTeV, "c"–CERN CPLEAR, "d"–FNAL E773, "e"–FNAL E731, "f"–CERN, "g"–CERN NA31, and are cited in Table 1. The narrow band "j" shows ϕ_{SW}. The ellipse "a" shows the $\chi^2 = 1$ contour of the fit result.

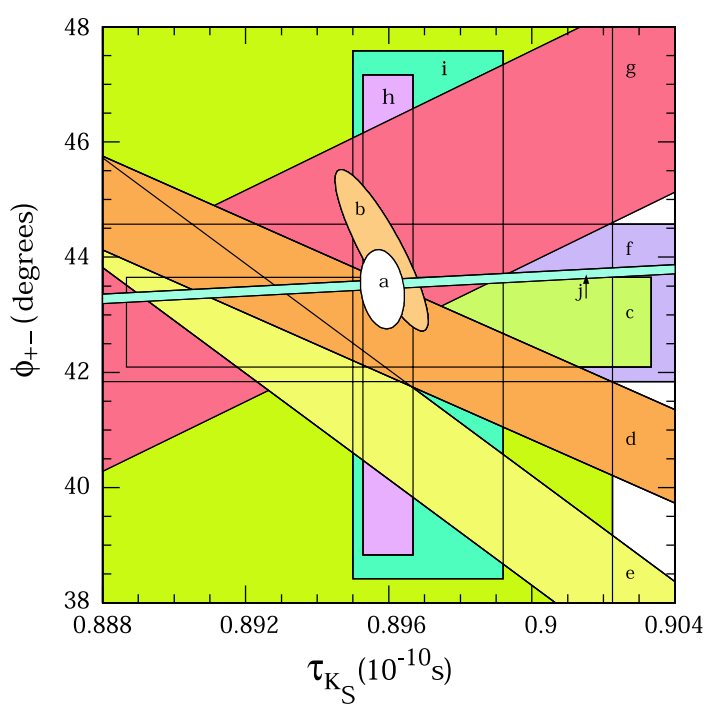

Figure 2: ϕ_{+-} vs τ_s. τ_s measurements appear as vertical bands spanning $\tau_s \pm 1\sigma$, some of which are cut near the top and bottom to aid the eye. Most ϕ_{+-} measurements appear as diagonal or horizontal bands spanning $\phi_{+-} \pm \sigma_\phi$. Data are labeled by letters: "b"–FNAL KTeV, "c"–CERN CPLEAR, "d"–FNAL E773, "e"–FNAL E731, "f"–CERN, "g"–CERN NA31, "h"–CERN NA48, "i"–CERN NA31, and are cited in Table 1. The narrow band "j" shows ϕ_{SW}. The ellipse "a" shows the fit result's $\chi^2 = 1$ contour.

D^0–$\overline{D}^0$ Mixing (p.679)

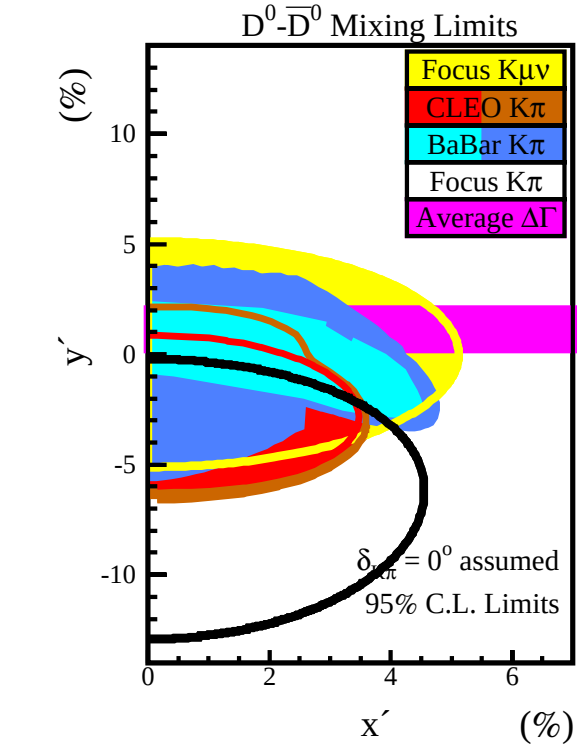

Figure 1: Current allowed regions in the plane of y' versus x'. The regions for CLEO and BaBar allow CP violation in the decay amplitude, in the mixing amplitude, and in the interference between these two processes. The FOCUS result does not allow CP violation. The allowed region for $\Delta\Gamma$ is the average of the y_{CP} [26, 28–31] results and the BABAR measurement of $y\cos\phi$ [27] and does not include $y = 0$. We assume $\delta = 0$ to place the $\Delta\Gamma$ results. A non-zero value for δ would rotate this confidence region clockwise about the origin by an angle δ.

B^0–$\overline{B}^0$ Mixing (p.763)

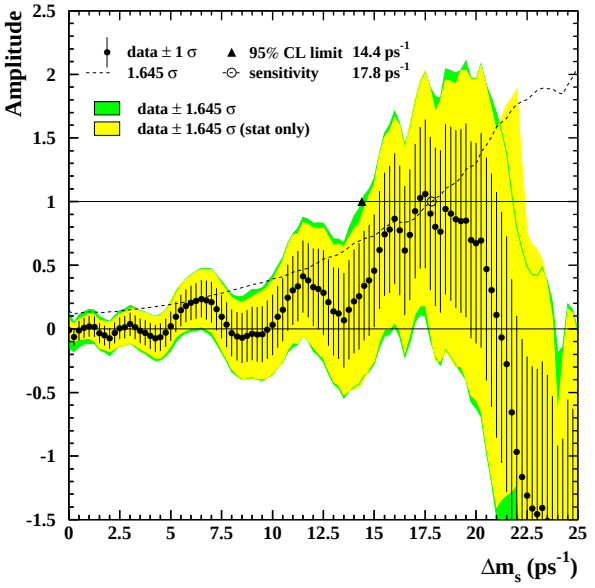

Figure 2: Combined measurements of the B_s^0 oscillation amplitude as a function of Δm_s, including all results published by November 2003. The measurements are dominated by statistical uncertainties. Neighboring points are statistically correlated.

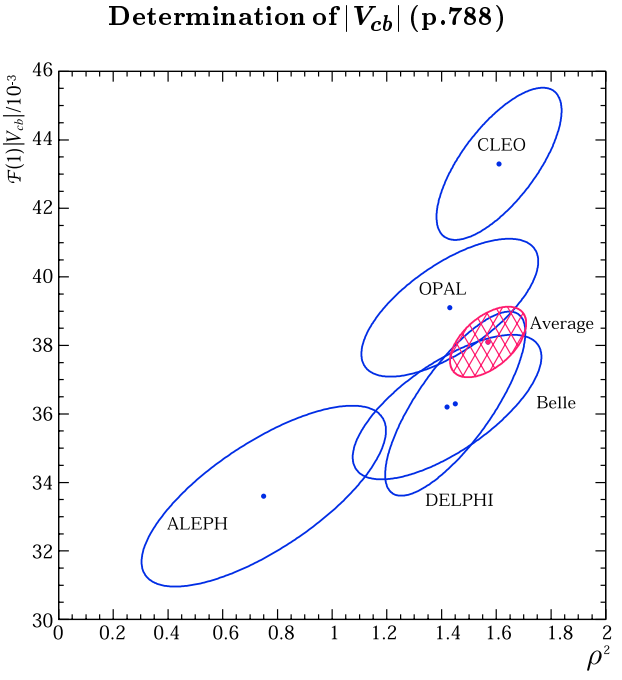

Figure 1: The error ellipses for the corrected measurements and world average for $\mathcal{F}(1)|V_{cb}|$ vs ρ^2. The ellipses are the product between the 1 σ error of $\mathcal{F}(1)|V_{cb}|$, ρ^2, and the correlation between the two.

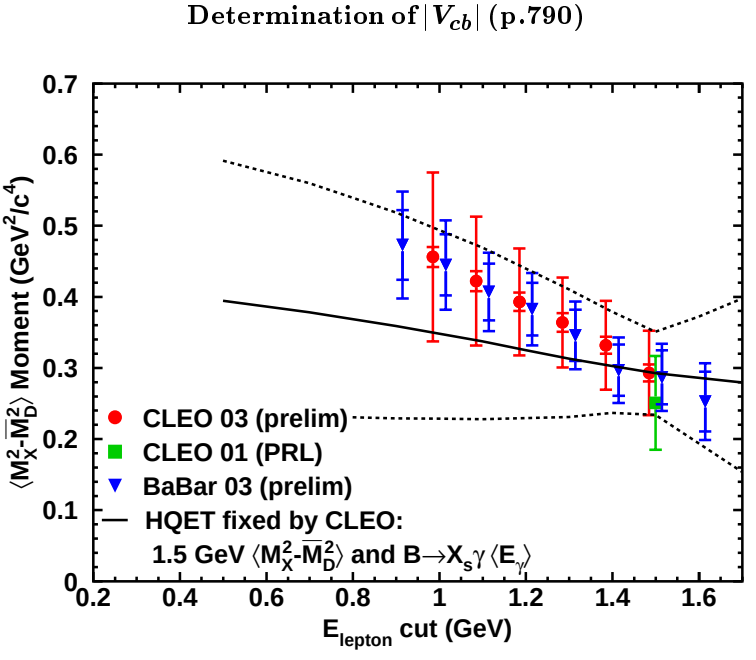

Figure 2: The results of the recent CLEO analysis [59] compared to previous measurements [55,60] and the HQET prediction. The theory bands shown in the figure reflect the variation of the experimental errors on the two constraints, the variation of the third-order HQET parameters by the scale $(0.5\ \mathrm{GeV})^3$, and variation of the size of the higher order QCD radiative corrections [56].

Supersymmetry, Part II (Experiment, p.1016)

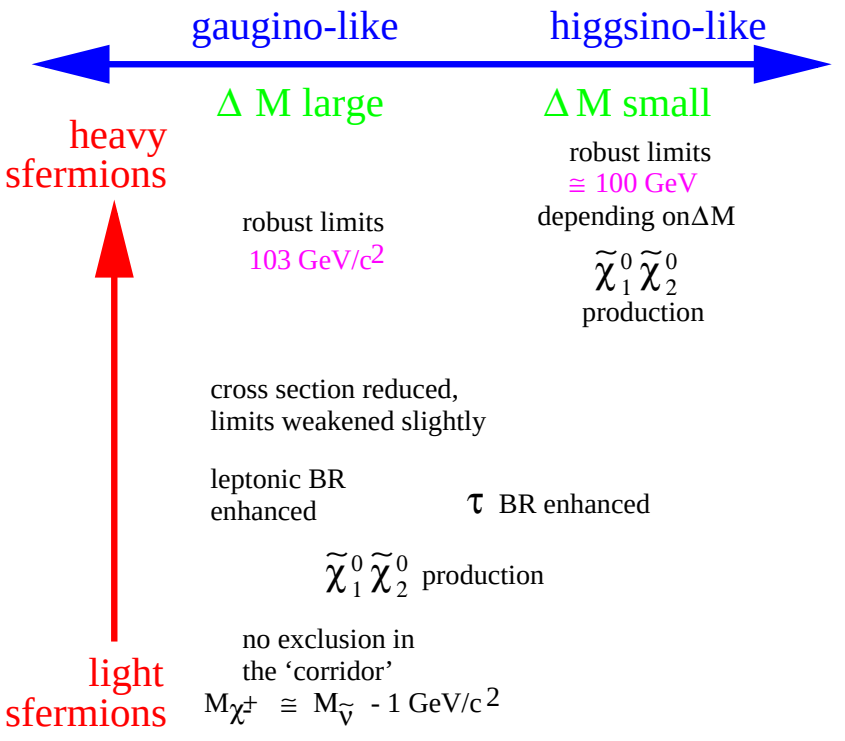

Figure 1: Heuristic diagram of the interplay of chargino field content and sfermion masses.

Supersymmetry, Part II (Experiment, p.1019)

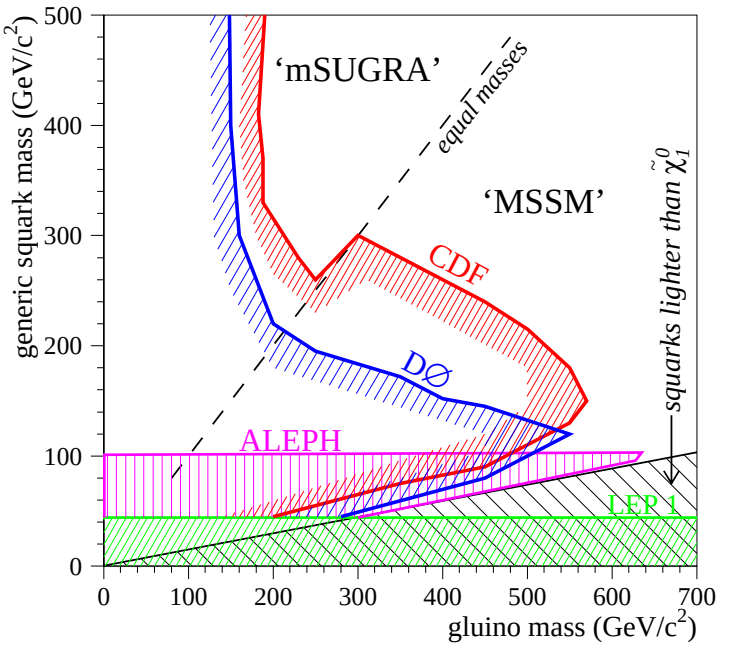

Figure 2: Regions in the $M_{\tilde{g}}$-$M_{\tilde{q}}$ plane excluded by searches for jets and missing energy at CDF, DØ, and LEP.

Supersymmetry, Part II (Experiment, p.1020)

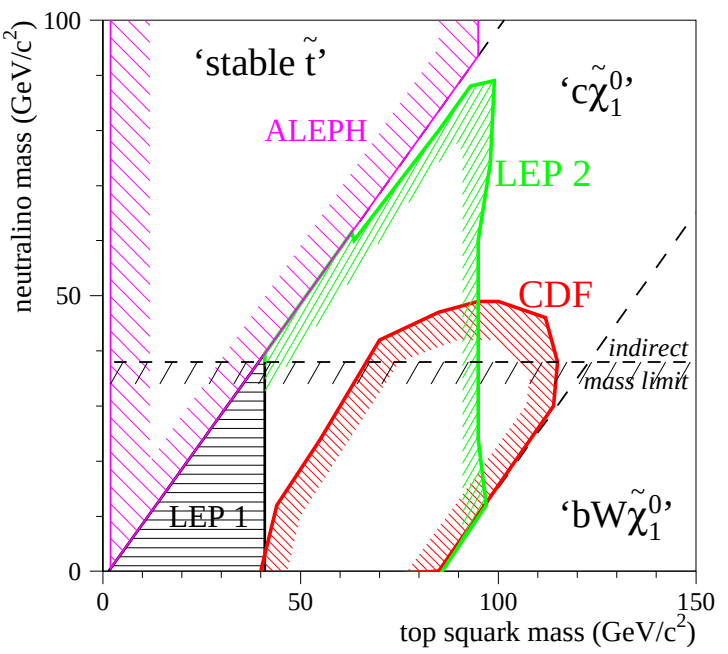

Figure 3: Regions excluded in the ($M_{\tilde{t}_1}$,$M_{\tilde{\chi}}$) plane. The results for the $c\tilde{\chi}_1^0$ decay mode are displayed from LEP and CDF. A DELPHI result for stable stops is indicated for $M_{\tilde{t}_1} < M_{\tilde{\chi}}$. Finally, the indirect limit on $M_{\tilde{\chi}}$ is also shown. There is effectively no exclusion in the region where $\tilde{t}_1 \to bW\tilde{\chi}_1^0$.

Dynamical Electroweak Symmetry Breaking (p.1041)

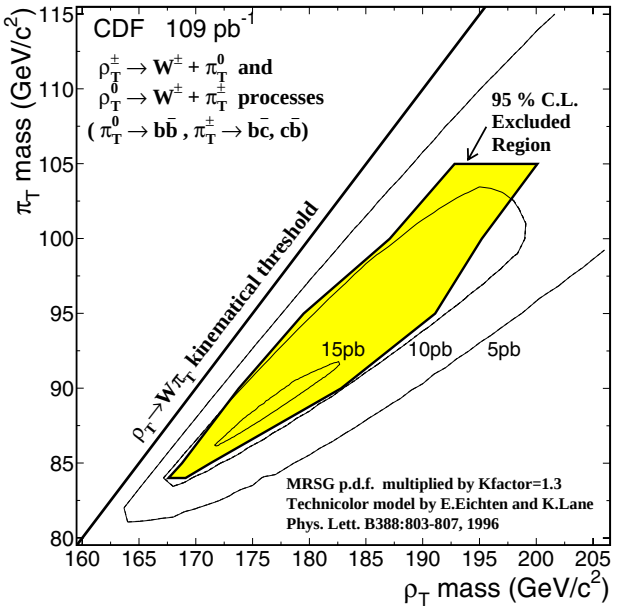

Figure 1: 95% CL exclusion region [16] for a light technirho decaying to $W^{\pm}$ and a π_T, and in which the π_T decays to two jets including at least one b quark.

Dynamical Electroweak Symmetry Breaking (p.1042)

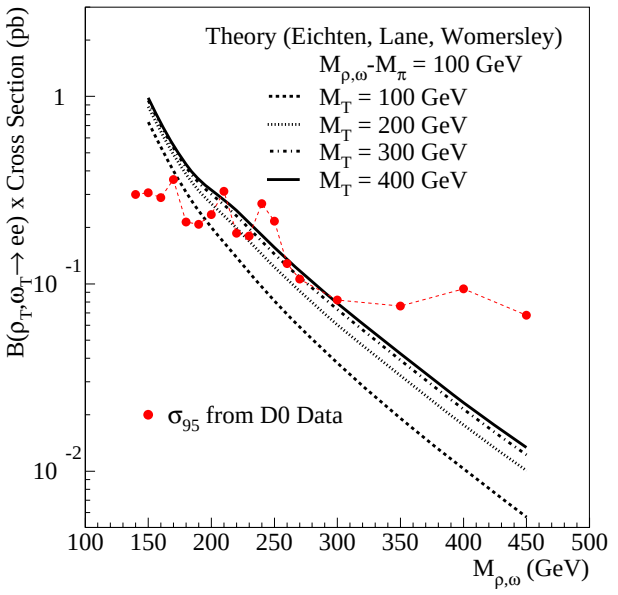

Figure 3: 95% CL cross-section limit [19] for a light techniomega and a light technirho decaying to $\ell^+\ell^-$.

Dynamical Electroweak Symmetry Breaking (p.1043)

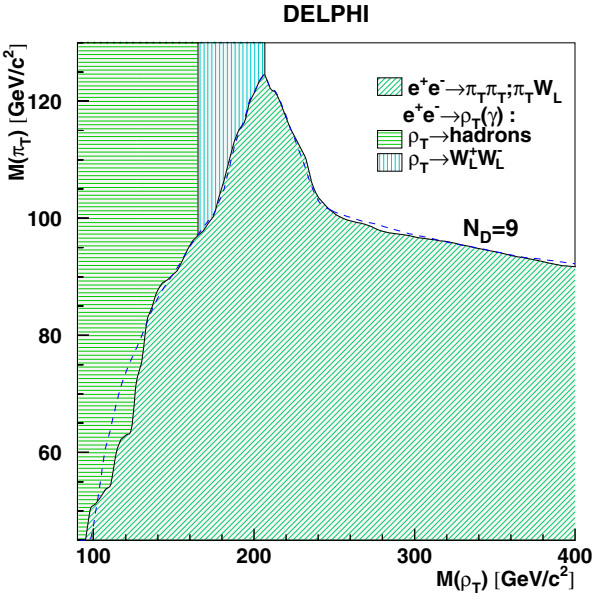

Figure 4: 95% CL exclusion region [20] in the technirho-technipion mass plane obtained from searches by the DELPHI collaboration at LEP 2, for nine technifermion doublets. The dashed line shows the expected limit for the 4-jet analysis.

Dynamical Electroweak Symmetry Breaking (p.1044)

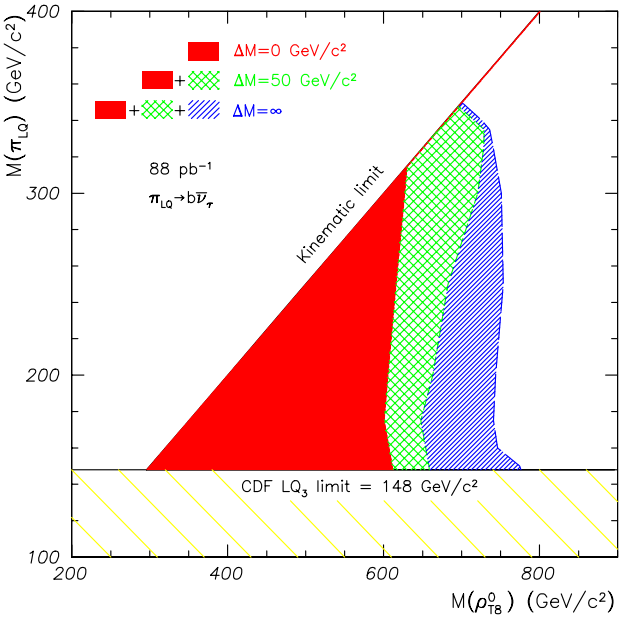

Figure 6: 95% CL exclusion region [25] in the technirho-technipion mass plane for pair produced technipions, with leptoquark couplings, decaying to $b\nu$.
